Introduction vii

Part I Thermodynamics

1. Thermodynamic States and the First Law (1001-1030)

2. The Second Law and Entropy (1031-1072)

3. Thermodynamic Functions and Equilibrium Conditions

4. Change of Phase and Phase Equilibrium (1106-1147)

5. Nonequilibrium Thermodynamics (1148-1159)

PART I THERMODYNAMICS

1. THERMODYNAMIC STATES AND THE FIRST LAW (1001-1030)

1001

Describe briefly the basic principle of the following instruments for making temperature measurements and state in one sentence the special usefulness of each instrument: constant-volume gas thermometer, thermocouple, thermistor.

(*Wisconsin*)

Solution:

Constant-volume gas thermometer: It is made according to the principle that the pressure of a gas changes with its temperature while its volume is kept constant. It can approximately be used as an ideal gas thermometer.

Thermocouple thermometer: It is made according to the principle that thermoelectric motive force changes with temperature. The relation between the thermoelectric motive force and the temperature is

$$\varepsilon = a + bt + ct^2 + dt^3,$$

where ε is the electric motive force, t is the difference of temperatures of the two junctions, a, b, c and d are constants. The range of measurement of the thermocouple is very wide, from **-2000C** to **1600C**. It is used as a practical standard thermometer in the range from **630.74°C** to **1064.43°C**.

Thermistor thermometer: We measure temperature by measuring the resistance of a metal. The precision of a thermistor made of pure platinum is very good, and its range of measurement is very wide, so it is usually used as a standard thermometer in the range from **13.81K** to **903.89K**.

1002

Describe briefly three different instruments that can be used for the accurate measurement of temperature and state roughly the temperature range in which they are useful and one important advantage of each instrument. Include at least one instrument that is capable of measuring temperatures down to **1K**.

(Wisconsin)

3

4 Problems on Thermodynamics & Statistical Mechanics

Solution:

1. Magnetic thermometer: Its principle is Curie's law $\chi = C/T$, where χ is the susceptibility of the paramagnetic substance used, T is its absolute temperature and C is a constant. Its advantage is that it can measure temperatures below 1K.
2. Optical pyrometer: It is based on the principle that we can find the temperature of a hot body by measuring the energy radiated from it, using the formula of radiation. While taking measurements, it does not come into direct contact with the measured body. Therefore, it is usually used to measure the temperatures of celestial bodies.
3. Vapor pressure thermometer: It is a kind of thermometer used to measure low temperatures. Its principle is as follows. There exists a definite relation between the saturation vapor pressure of a chemically pure material and its boiling point. If this relation is known, we can determine temperature by measuring vapor pressure. It can measure temperatures greater than 14K, and is the thermometer usually used to measure low temperatures.

1003

A bimetallic strip of total thickness z is straight at temperature T . What is the radius of curvature of the strip, R , when it is heated to temperature $T + \Delta T$? The coefficients of linear expansion of the two metals are α_1 and α_2 , respectively, with $\alpha_2 > \alpha_1$. You may assume that each metal has thickness $z/2$, and you may assume that $z \ll R$.

(Wisconsin)

Solution:

We assume that the initial length is l_0 . After heating, the lengths of the mid-lines of the two metallic strips are respectively

Thermodynamics 5

Fig. 1.1.

Assuming that the radius of curvature is R , the subtending angle of the strip is θ , and the change of thickness is negligible, we have

$$z = \frac{1}{2} z_1 + \frac{1}{2} z_2$$

$$z - \frac{1}{2} z = \frac{1}{2} z = \frac{1}{2} z (\alpha_1 + \alpha_2) \Delta T$$

$$z = 2R \theta \quad (3)$$

From (1) and (2) we obtain

(3) and (4) then give

1004

An ideal gas is originally confined to a volume V_1 in an insulated container of volume $V_1 + V_2$. The remainder of the container is evacuated. The partition is then removed and the gas expands to fill the entire container.

If the initial temperature of the gas was T , what is the final temperature?

Justify your answer.

(Wasconsin)

insulated container C

Fig. 1.2.

6 Problem, 4 Solutions on Thermodynamics & Statistical Mechanics

Solution:

This is a process of adiabatic free expansion of an ideal gas. The internal energy does not change; thus the temperature does not change,

that is, the final temperature is still T .

1005

An insulated chamber is divided into two halves of volumes. The left half contains an ideal gas at temperature T_0 and the right half is evacuated. A small hole is opened between the two halves, allowing the gas to flow through, and the system comes to equilibrium. No heat is exchanged with the walls. Find the final temperature of the system.

(Columbia)

Solution:

After a hole has been opened, the gas **flows** continuously to the right side and reaches equilibrium finally. During the process, internal energy of the system E is unchanged. Since E depends on the temperature T only for an ideal gas, the equilibrium temperature is still T_0 .

Fig. 1.3.

1006

Define heat capacity C , and calculate from the first principle the numerical value (in calories/C) for a copper penny in your pocket, using your best physical knowledge or estimate of the needed parameters.

(UC, Berkeley)

Solution:

penny is about 32 g, i.e., 0.5 mol. Thus $C = 0.5 \times 3R = 13 \text{ J/K}$.

$C_p = (dQ/dT)$. The atomic number of copper is 64 and a copper

Thermodynamics 7

1007

Specific heat of granite may be: 0.02, 0.2, 20, 2000 cal/g.K.

(Columbia)

Solution:

The main component of granite is CaCO_3 ; its molecular weight is 100.

The specific heat is $C = 3R/100 = 0.25 \text{ cal/g.K}$. Thus the best answer is 0.2 cal/g.K.

1008

The figure below shows an apparatus for the determination of C_p/C_v for a gas, according to the method of Clement and Desormes. A bottle G, of reasonable capacity (say a few litres), is fitted with a tap H, and a manometer M. The difference in pressure between the inside and the outside can thus be determined by observation of the difference h in heights of the two columns in the manometer. The bottle is filled with the gas to be investigated, at a very slight excess pressure over the outside atmospheric pressure. The bottle is left in peace (with the tap closed) until the temperature of the gas in the bottle is the same as the outside temperature in the room. Let the reading of the manometer be h_1 . The tap H is then opened for a very short time, just sufficient for the internal pressure to become equal to the atmospheric pressure (in which case the manometer reads $h = 0$). With the tap closed the bottle is left in peace for a while, until the inside temperature has become equal to the outside temperature. Let the final reading of the manometer be h_2 . From the values of h_1 and h_2 , it is possible to find C_p/C_v . (a) Derive an expression for C_p/C_v in terms of h_1 and h_2 in the above experiment. (b) Suppose that the gas in question is oxygen. What is your theoretical prediction for C_p/C_v at 20°C , within the framework of statistical mechanics?

(UC, Berkeley)

h

Fig. 1.4.

0 Problems 8 Sdutoru on Thermodyurmica 8 Statiaticd Mechanics

Solution:

(a) The equation of state of ideal gas is $pV = nkT$. Since the initial

and final T, V of the gas in the bottle are the same, we have $p_f/p_i = n_f/n_i$.
 Meanwhile, $n_f/n_i = V/V'$, where V' is the volume when the initial gas in the bottle expands adiabatically to pressure p_0 . Therefore

$$\gamma = \frac{C_p}{C_v} = \frac{f+2}{f}$$

Since $h_i/h_0 \ll 1$ and $hf/h_0 \ll 1$, we have $\gamma = h_i/(h_i - hf)$.

(b) Oxygen consists of diatomic molecules. When $t = 200^\circ\text{C}$, only the translational and rotational motions of the molecules contribute to the specific heat. Therefore

1009

(a) Starting with the first law of thermodynamics and the definitions of c_p and c_v , show that

$$c_p - c_v = R \quad \left(\frac{\text{J}}{\text{mol}\cdot^\circ\text{C}}\right)$$

where c_p and c_v are the specific heat capacities per mole at constant pressure and volume, respectively, and U and V are energy and volume of one mole.

(b) Use the above results plus the expression

$$p + \frac{a}{V^2} = \frac{RT}{V - b}$$

to find $c_p - c_v$ for a Van der Waals gas

Use that result to show that as $V \rightarrow \infty$ at constant p , you obtain the ideal gas result for $c_p - c_v$.

(SUNY, Buffalo)

Thermodynamics 9

Solution:

(a) From $H = U + pV$, we obtain

$$\left(\frac{\partial H}{\partial T}\right)_p = \left(\frac{\partial U}{\partial T}\right)_p + p \left(\frac{\partial V}{\partial T}\right)_p$$

Let $U = U(T, V)$. The above expression becomes

Hence

R

(b) For the Van der Waals gas, we have

R

$$RT - \frac{2a}{V} = p(V - b)$$

v^3

Hence,

R

$$c_p - c_v =$$

$$R - \frac{2a(1 - b/V)^2}{VRT^2}$$

When $V \rightarrow \infty$, $c_p - c_v \rightarrow R$, which is just the result for an ideal gas.

1010

One mole of gas obeys Van der Waals equation of state. If its molar internal energy is given by $u = cT - a/V$ (in which V is the molar volume, a is one of the constants in the equation of state, and c is a constant), calculate the molar heat capacities C_p and C_v .

Solution:

(was constant)

$$C_v = \left(\frac{\partial u}{\partial T}\right)_v = c$$

$$C_p = \left(\frac{\partial u}{\partial T}\right)_p + p \left(\frac{\partial V}{\partial T}\right)_p = R + \frac{a}{V^2} \quad \left[\left(\frac{\partial}{\partial T}\right)_p \left(\frac{a}{V}\right) = -\frac{a}{V^2} \left(\frac{\partial V}{\partial T}\right)_p\right]$$

v

$$C_p - C_v = R + \frac{2a}{V^2} \left(\frac{\partial V}{\partial T}\right)_p$$

A solid object has a density ρ , mass M, and coefficient of linear expansion

a. Show that at pressure p the heat capacities C , and $C_{,}$, are related

bY

$$C , - C_{,} = 3aMp/p .$$

(Wisconsin)

Soh tion:

From the first law of thermodynamics $dQ = dU + pdV$ and $(\%) , -$

(g) , , (for solid), we obtain

$$C , - c '' = (g) , - (g) = p \ $dVT .$$

From the definition 1 dV of coefficient of linear expansion $a = asolid/3 = - -$
 $3V dT'$

we obtain M

$$- = 3aV = 3a - . dV$$

$dT P$

Substituting this in (*), we find

M

P

$$C , - C_{,} = 3a-p .$$

Thermdyomics 11

1012

One mole of a monatomic perfect gas initially at temperature T_0 expands

from volume V_0 to $2V_0$ (a) at constant temperature, (b) at constant

pressure.

Calculate the work of expansion and the heat absorbed by the gas in

each case.

(Wisconsin)

Solution:

(a) At constant temperature T_0 , the **work** is

$2v_0$

$$W = L B pdV = RT_0 \mathbf{lo} \ d V / V = RT_0 \mathbf{ln} 2 .$$

As the change of the internal energy is zero, the heat absorbed by the gas

is

$$Q = W = RT_0 \mathbf{ln} 2 .$$

(b) At constant pressure p , the **work** is

The increase of the internal energy is

3 3 3

2 2 2

$$\Delta U = C_V \Delta T = -R \Delta T = -p \Delta V = -p V \Delta$$

$$3 - R T_0 \cdot 2$$

Thus the heat absorbed by the gas is

5

2

$$Q = \Delta U + W = -R T_0$$

101s

For a diatomic ideal gas near room temperature, what fraction of the heat supplied is available for external work if the gas is expanded at constant pressure? At constant temperature?

(Wisconsin)

12 Problem 8 Solutions on Thermodynamic 3 4 Statistical Mechanics

Solution:

In the process of expansion at constant pressure p , assuming that the volume increases from V_1 to V_2 and the temperature changes from T_1 to T_2 , we have

$$pV_1 = nRT_1 \quad \left\{ \quad pV_2 = nRT_2 \right.$$

In this process, the work done by the system on the outside world is $W = p(V_2 - V_1) = nR \Delta T$ and the increase of the internal energy of the system is

$$\Delta U = C_V \Delta T$$

Therefore

W 2

$$Q = \Delta U + W = C_V \Delta T + nR \Delta T$$

--

$$\frac{W}{Q} = \frac{nR}{C_V + nR}$$

In the process of expansion at constant temperature, the internal energy does not change. Hence

$$W / Q = 1$$

1014

A compressor designed to compress air is used instead to compress helium. It is found that the compressor overheats. Explain this effect, assuming the compression is approximately adiabatic and the starting pressure is the same for both gases.

(wis **cons in**)

Solution:

The state equation of ideal gas is

$$pV = nRT$$

The equation of adiabatic process is

$$P (\gamma)^\gamma = P_0$$

where $\gamma = c_P/c_V$, p_0 and p are starting and final pressures, respectively, and

V_0 and V are volumes. Because $V_0 > V$ and $\gamma_{He} > \gamma_{Air}$ ($\gamma = 7/5$; $\gamma_{Air} = 5/3$), we get

$$P_{He} > P_{Air} \text{ and } T_{He} > T_{Air}$$

Thermodynamics 13

1015

Calculate the temperature after adiabatic compression of a gas to 10.0 atmospheres pressure from initial conditions of 1 atmosphere and 300K (a) for air, (b) for helium (assume the gases are ideal).

Solution:

(Wisconsin)

The adiabatic process of an ideal gas follows the law

$$T_B = (p_B/p_A)^{\gamma-1} T_A = 10^{(7-1)/7} \times 300 \text{ K}$$

(a) For air, $\gamma = C_p/C_v = 1.4$, thus $T_B = 5.8 \times 10^3 \text{ K}$.

(b) For helium, $\gamma = C_p/C_v = 5/3$, thus $T_B = 7.5 \times 10^2 \text{ K}$.

1016

(a) For a mole of ideal gas at $t = 0^\circ\text{C}$, calculate the work W done (in Joules) in an isothermal expansion from V_0 to $10V_0$ in volume.

(b) For an ideal gas initially at $t_i = 0^\circ\text{C}$, find the final temperature t_f (in $^\circ\text{C}$) when the volume is expanded to $10V_0$ reversibly and adiabatically.

(UC, Berkeley)

Solution:

$$pdV = -dV = RT \ln 10 = 5.2 \times 10^3 \text{ J}$$

(b) Combining the equation of adiabatic process $pV^\gamma = \text{const}$ and the equation of state $pV = RT$, we get $TV^{\gamma-1} = \text{const}$. Thus

If the ideal gas molecule is monatomic, $\gamma = 5/3$, we get $t_f = 59 \text{ K}$ or -214°C .

1017

(a) How much heat is required to raise the temperature of 1000 grams

(b) How much has the internal energy of the nitrogen increased?

(c) How much external work was done?

of nitrogen from -20°C to 100°C at constant pressure?

14 Problem 4 Solution on Thermodynamics & Statistical Mechanics

(d) How much heat is required if the volume is kept constant?

Take the specific heat at constant volume $c_v = 5 \text{ cal/mole } ^\circ\text{C}$ and

$R = 2 \text{ cal/mole } ^\circ\text{C}$.

(Wisconsin)

Solution:

(a) We consider nitrogen to be an ideal gas. The heat required is 1000

28

$$Q = n(c_v + R)\Delta T = (5 + 2) \times 120 = 30 \times 10^3 \text{ cal}$$

(b) The increase of the internal energy is

100

28

$$\Delta U = n c_v \Delta T = 5 \times 120$$

$$= 2.1 \times 10^3 \text{ cal}$$

(c) The external work done is

$$W = Q - \Delta U = 8.6 \times 10^3 \text{ cal}$$

(d) If it is a process of constant volume, the required heat is

$$Q = n c_v \Delta T = 2.1 \times 10^3 \text{ cal}$$

1018

10 litres of gas at atmospheric pressure is compressed isothermally to a volume of 1 litre and then allowed to expand adiabatically to 10 litres.

(a) Sketch the processes on a pV diagram for a monatomic gas.

(b) Make a similar sketch for a diatomic gas.

(c) Is a net work done on or by the system?

(d) Is it greater or less for the diatomic gas?

(Wisconsin)

Solution:

We are given that $V_A = 10 \text{ L}$, $V_B = 1 \text{ L}$, $V_C = 10 \text{ L}$ and $p_A = 1 \text{ atm}$.

$A \rightarrow B$ is an isothermal process, thus

$$pV = \text{const. or } p_A V_A = p_B V_B$$

hence
 V_A
 V_B

$$p \sim \dots p_A = 10 \text{ atm} .$$

(The curve AB of the two kinds of gas are the same).

$B \rightarrow C$ is an adiabatic process, thus

$$pV^\gamma = \text{const}, \text{ or } p \sim V^{-\gamma} = p_C V_C^\gamma, \text{ hence}$$

(a) For the monatomic gas, we have

$$\gamma = 5/3, p_C = 10 \cdot 2^{3/2} = 0.215 \text{ atm} .$$

(b) For the diatomic gas, we have

$$\gamma = 7/5, p_C = 10 \cdot 2^{5/2} = 0.398 \text{ atm} .$$

The two processes are shown in the figures 1.5. (The curve BC of the monatomic gas (a) is lower than that of the diatomic gas (b)).

(c) In each case, as the curve AB for compression is higher than the curve BC for expansion, net work is done on the system. As p_C (monatomic gas) $<$ p_C (diatomic gas) the work on the monatomic gas is greater than that on the diatomic gas.

1.6 Problem 8' Solutions on Thermodynamics 8' Statics Mechanics

1019

An ideal gas is contained in a large jar of volume V_0 . Fitted to the jar is a glass tube of cross-sectional area A in which a metal ball of mass M fits snugly. The equilibrium pressure in the jar is slightly higher than atmospheric pressure p_0 because of the weight of the ball. If the ball is displaced slightly from equilibrium it will execute simple harmonic motion (neglecting friction). If the states of the gas represent a quasistatic adiabatic process and γ is the ratio of specific heats, find a relation between the oscillation frequency f and the variables of the problem.

(UC, Berkeley)

Fig. 1.6.

Solution:

have

Assume the pressure in the jar is p . As the process is adiabatic, we

$$pV^\gamma = \text{const} ,$$

giving

$$dp dV$$

$$- \gamma p dV = 0 .$$

$$p dV$$

This can be written as $F = Adp = -kz$, where F is the force on the ball,

$$z = dV/A \text{ and } k = \gamma A^2 p/V. \text{ Noting that } p = p_0 + mg/A, \text{ we obtain}$$

1020

The speed of longitudinal waves of small amplitude in an ideal gas is

Thermodynamics 17

where p is the ambient gas pressure and ρ is the corresponding gas density.

Obtain expressions for

- (a) The speed of sound in a gas for which the compressions and rarefactions are isothermal.
 (b) The speed of sound in a gas for which the compressions and rarefactions are adiabatic.

(Wisconsin)

Solution:

The isothermal process of an ideal gas follows $pV = \text{const}$; the adiabatic process of an ideal gas follows $pV^\gamma = \text{const}$. We shall use $pV^t = \text{const}$ for a general process, its differential equation being

$$dp + t \frac{p}{V} dV = 0.$$

pV

Thus $(2) = -t \frac{dp}{p} = -t \frac{dV}{V}$.

With $p = M/V$, we have

RT

Therefore

(a) The isothermal process: $t = 1$, thus $c = \frac{dM}{M} = \frac{dV}{V}$.

(b) The adiabatic process: $t = \gamma$, thus $c = \frac{dM}{M} = \frac{dV}{V} \gamma$.

1021

Two systems with heat capacities C_1 and C_2 , respectively, interact thermally and come to a common temperature T_f . If the initial temperature of system 1 was T_1 , what was the initial temperature of system 2? You may assume that the total energy of the combined systems remains constant.

(Wisconsin)

18 Problems in Thermodynamics and Statistical Mechanics

Solution:

We assume that the initial temperature of system 2 is T_2 . According to the conservation of energy, we know the heat released from system 1 is equal to that absorbed by the other system, i.e.,

The solution is

C1

C_2

$$T_2 = -\frac{(C_1 T_1 - C_2 T_f)}{C_2} + T_f.$$

1022

A large solenoid coil for a physics experiment is made of a single layer of conductor of cross section 4cm X 2cm with a cooling water hole 2 cm X 1cm in the conductor. The coil, which consists of 100 turns, has a diameter of 3 meters, and a length of 4 meters (the insulation thickness is negligible). At the two ends of the coil are circular steel plates to make the field uniform and to return the magnetic flux through a steel cylindrical structure external to the coil, as shown in the diagram. A magnetic field of 0.25 Tesla is desired. The conductor is made of aluminium.

- (a) What power (in kilowatts) must be supplied to provide the desired field, and what must be the voltage of the power supply?
 (b) What rate of water flow (litres/second) must be supplied to keep the temperature rise of the water at 40°C? Neglect all heat losses from the coil except through the water.
 (c) What is the outward pressure exerted on the coil by the magnetic forces?
 (d) If the coil is energized by connecting it to the design voltage calculated in (a), how much time is required to go from zero current to 99% of the design current? Neglect power supply inductance and resistance. The

resistivity of aluminium is 3×10^{-8} ohm-meters. Assume that the steel is far below saturation.

(CUSPEA)

Thermodynamics 19

----- cooling - 7

coil in detail

Fig. 1.7.

Solution:

where N is the number of turns, L is the length of the solenoid coil. The current is therefore

(a) The magnetic field is $B = \mu_0 NI/L$,

$$I = \frac{B \cdot L}{\mu_0 \cdot N} = \frac{0.25 \times 4}{4\pi \times 10^{-7} \times 100} = 7960 \text{ A}$$

$$\mu_0 = 4\pi \times 10^{-7} \times 100$$

The total resistance of the coil is $R = \rho L/A$. Therefore, the resistance, the voltage and the power are respectively

$$R = \frac{\rho L}{A} = \frac{(3 \times 10^{-8})(100 \times 2 \times 1.5)}{(4 \times 2 \times 1) \times 10^{-4}} = 0.0471 \Omega$$

$$R = 0.0471 \Omega$$

$$(4 \times 2 \times 1) \times 10^{-4}$$

$$V = RI = 375 \text{ V}$$

$$P = VI = 2.99 \times 10^3 \text{ kW}$$

(b) The rate of flow of the cooling water is W . Then $\rho W C \Delta T = P$, where ρ is the density, C is the specific heat and ΔT is the temperature rise of the water. Hence

$$2.99 \times 10^3 \times 10^3$$

$$P = 17.8 \text{ l/s}$$

$\rho C \Delta T$

$$W = \frac{P}{\rho C \Delta T}$$

$$1 \times 4190 \times 40$$

(c) The magnetic pressure is

$$(0.25)^2$$

$$= 2.49 \times 10^4 \text{ N/m}^2 \cdot B^2$$

$$2\mu_0 \cdot \frac{1}{2} \cdot (4\pi \times 10^{-7})$$

$$p = \frac{B^2}{2\mu_0}$$

20 Problem El Sdutiom on Thermodynamics 8 Statistical Mechanica

(d) The time constant of the circuit is

$$\tau = L/R, \text{ with } L = N^2 \mu_0 / l,$$

where L is the inductance, R is the resistance, N is the number of turns, I is the current and Φ is the magnetic flux. Thus we have

$$L = 100^2 \times 0.25 \times (1.5) / 7960 = 0.0222 \text{ H}$$

and

$$\tau = 0.0222 / 0.0471 = 0.471 \text{ s}$$

The variation of the current before steady state is reached is given by

$$I(t) = I_{\max} [1 - \exp(-t/\tau)]$$

$$\text{When } I(t) / I_{\max} = 99\%,$$

$$t = \tau \ln 100 = 4.67 \times 0.471 = 2.17 \text{ s}$$

102s

Consider a black sphere of radius R at temperature T which radiates to distant black surroundings at $T = 0 \text{ K}$.

(a) Surround the sphere with a nearby heat shield in the form of a black

shell whose temperature is determined by radiative equilibrium. What is the temperature of the shell and what is the effect of the shell on the total power radiated to the surroundings?

(b) How is the total power radiated affected by additional heat shields?

(UC, Berkeley)

(a) At radiative equilibrium, $J = \sigma_1 = J_1$ or $\sigma_1 = 512$. Therefore (Note that this is a crude model of a star surrounded by a dust cloud.)

Solution:

$$T_f = T_4/2, \text{ or } T_1 =$$

Fig. 1.8.

Thermodynamics 21

(b) The heat shield reduces the total power radiated to half of the initial value. This is because the shield radiates a part of the energy it absorbs back to the black sphere.

1024

In vacuum insulated cryogenic vessels (Dewars), the major source of heat transferred to the inner container is by radiation through the vacuum jacket. A technique for reducing this is to place "heat shields" in the vacuum space between the inner and outer containers. Idealize this situation by considering two infinite sheets with emissivity = 1 separated by a vacuum space. The temperatures of the sheets are T_1 and T_2 ($T_2 > T_1$).

Calculate the energy flux (at equilibrium) between them. Consider a third sheet (the heat shield) placed between the two which has a reflectivity of R . Find the equilibrium temperature of this sheet. Calculate the energy flux from sheet 2 to sheet 1 when this heat shield is in place.

For $T_2 =$ room temperature, $T_1 =$ liquid He temperature (4.2 K) find the temperature of a heat shield that has a reflectivity of 95%. Compare the energy flux with and without this heat shield.

$$\epsilon = 0.55 \times 10^{-7} \text{ watts/m}^2\text{K}$$

(UC, Berkeley)

Fig. 1.9.

Solution:

When there is no "heat shield", the energy flux is

When a "heat shield" is added, we have

$$J' = E_2 - RE, - (1 - R)E_3,$$

$$J' = (1 - R)E_3 + RE_1 - E_1.$$

22

These equations imply $E_3 = (E_1 + E_2)/2$, or $T_3 = [(T_1^4 + T_2^4)/2]^{1/4}$. Hence

Problems 8 Solution on Thermodynamics & Statistical Mechanics

$$J^* = (1 - R)(E_2 - E_1)/2 = (1 - R) J/2.$$

With $T_1 = 4.2$ K, $T_2 = 300$ K and $R = 0.95$, we have

$$T_3 = 252 \text{ K and } J^*/J = 0.025.$$

1025

Two parallel plates in vacuum, separated by a distance which is small compared with their linear dimensions, are at temperatures T_1 and T_2 respectively ($T_1 > T_2$).

(a) If the plates are non-transparent to radiation and have emission powers e_1 and e_2 respectively, show that the net energy W transferred per unit area per second is

$$E_1 - E_2$$

$$E_1 - E_2 W =$$

$$-+--1$$

where E_1 and E_2 are the emission powers of black bodies at temperatures

T_1 and T_2 respectively.

(b) Hence, what is W if T_1 is 300 K and T_2 is 4.2 K, and the plates are black bodies?

(c) What will W be if n identical black body plates are interspersed between the two plates in (b)?

$$\sigma = 5.67 \times 10^{-8} \text{ W/m}^2\text{K}^4.$$

(SUNY, Buflulo)

Solution:

reflection) of the two plates respectively. We have

(a) Let f_1 and f_2 be the total emission powers (thermal radiation plus

The solution is

Hence

$$E_1 - E_2$$

$$-E_1 + -E_2$$

$$W = f_1 - f_2 =$$

$$e_1 - e_2$$

(b) For black bodies, $W = E_1 - E_2 = u(T_1 - T_2) = 460 \text{ W/m}^2$.

(c) Assume that the n interspersed plates are black bodies at temperatures

t_1, t_2, \dots, t_n . When equilibrium is reached, we have

$$T - t_n = t_n - T_1, \text{ for } n = 1, \dots, n$$

with solution

with solution

Then in the general we have

$$T - t_n = t_n - T_1 = \dots = t_1 - T_1, \text{ with solution}$$

with solution

$$W = \sigma (T - T_1) = -\sigma (T_1 - T)$$

24 Problems in Solution on Thermodynamics and Statistical Mechanics

1026

A spherical black body of radius r at absolute temperature T is surrounded by a thin spherical and concentric shell of radius R , black on both sides. Show that the factor by which this radiation shield reduces the rate of cooling of the body (consider space between spheres evacuated, with no thermal conduction losses) is given by the following expression:

$$aR^2/(R^2 + br^2), \text{ and find the numerical coefficients } a \text{ and } b.$$

Solution:

black body before being surrounded by the spherical shell is

(SUNY, Buflulo)

Let the surrounding temperature be T_0 . The rate of energy loss of the

$$Q = 4\pi r^2 \sigma (T - T_0)$$

The energy loss per unit time by the black body after being surrounded by the shell is

$$Q' = 4\pi r^2 \sigma (T - T_1), \text{ where } T_1 \text{ is temperature of the shell.}$$

The energy loss per unit time by the shell is

$$Q'' = 4\pi R^2 \sigma (T_1 - T_0)$$

Since $Q'' = Q'$, we obtain

$$T_1 = (r^2 T^4 - t R^2 T_0^4) / (R^2 + r^2)$$

Hence $Q'/Q = R^2 / (R^2 + r^2)$, i.e., $a = 1$ and $b = 1$.

1027

The solar constant (radiant flux at the surface of the earth) is about 0.1 W/cm^2 . Find the temperature of the sun assuming that it is a black body.

Solution:

(MIT)

The radiant flux density of the sun is

$J = \sigma T^4$, where $\sigma = 5.7 \times 10^{-8} \text{ W/m}^2\text{K}^4$. Hence $T \sim (r_s / r_{SE})^2 J / \sigma$, where the radius of the sun $r_s = 7.0 \times 10^5 \text{ km}$, the distance between the earth and the sun $r_{SE} = 1.5 \times 10^8 \text{ km}$. Thus

1028

(a) Estimate the temperature of the sun's surface given that the sun subtends an angle θ as seen from the earth and the earth's surface temperature is T_0 . (Assume the earth's surface temperature is uniform, and that the earth reflects a fraction, E , of the solar radiation incident upon it). Use your result to obtain a rough estimate of the sun's surface temperature by putting in 'reasonable' values for all parameters.

(b) Within an unheated glass house on the earth's surface the temperature is generally greater than T_0 . Why? What can you say about the maximum possible interior temperature in principle?

(Columbia)

Solution:

(a) The earth radiates heat while it is absorbing heat from the solar radiation. Assume that the sun can be taken as a black body. Because of reflection, the earth is a grey body of emissivity $1 - E$. The equilibrium condition is

where J_s and J_E are the radiated energy flux densities on the surfaces of the sun and the earth respectively, R_s , R_E and r_{SE} are the radius of the sun, the radius of the earth and the distance between the earth and the sun respectively. Obviously $R_s/r_{SE} = \tan(\theta/2)$. From the Stefan-Boltzmann law, we have

for the sun, $J_s = \sigma T_s^4$;

for the earth $J_E = (1 - E)\sigma T_0^4$;

Therefore

$7 \times 10^6 \text{ km}$

$$T_s = T_0 \left(\frac{R_s}{r_{SE}} \right)^2 \frac{1}{\sqrt{1-E}}$$

$\approx 6000 \text{ K}$

26 Problem 4 Solutions on Thermodynamics & Statistical Mechanics

(b) Let T be temperature of the glass house and t be the transmission coefficient of glass. Then

$$(1 - t)\sigma T^4 + tT_0^4 = \sigma T^4,$$

giving

Since $t < 1$, we have $T > T_0$, so that

$$T > T_0$$

1029

Consider an idealized sun and earth, both black bodies, in otherwise empty flat space. The sun is at a temperature of $T_s = 6000 \text{ K}$ and heat transfer by oceans and atmosphere on the earth is so effective as to keep the earth's surface temperature uniform. The radius of the earth is $R_E = 6 \times 10^8 \text{ cm}$, the radius of the sun is $R_s = 7 \times 10^{10} \text{ cm}$, and the earth-sun distance is $d = 1.5 \times 10^{13} \text{ cm}$.

(a) Find the temperature of the earth.

(b) Find the radiation force on the earth.

(c) Compare these results with those for an interplanetary Uchondrulen

in the form of a spherical, perfectly conducting black-body with a radius of $R = 0.1 \text{ cm}$, moving in a circular orbit around the sun with a radius equal to the earth-sun distance d .

(Princeton)

Solution:

approximately

(a) The radiation received per second by the earth from the sun is

The radiation per second from the earth itself is

Thermodynamics 27

Neglecting the earth's own heat sources, energy conservation leads to the relation $Q_E = Q_{SE}$, so that

i.e.,

(b) The angles subtended by the earth in respect of the sun and by the sun in respect of the earth are very small, so the radiation force is

(c) $T_E = T_S = 17^\circ\text{C}$

$$F = (R/d)^2 Q_{SE} = 1.7 \times 10^{-1} \text{ N}$$

1030

Making reasonable assumptions, estimate the surface temperature of Neptune. Neglect any possible internal sources of heat. What assumptions have you made about the planet's surface and/or atmosphere?

Astronomical data which may be helpful: radius of sun = $7 \times 10^5 \text{ km}$; radius of Neptune = $2.2 \times 10^4 \text{ km}$; mean sun-earth distance = $1.5 \times 10^8 \text{ km}$; mean sun-Neptune distance = $4.5 \times 10^9 \text{ km}$; $T_S = 6000 \text{ K}$; rate at which sun's radiation reaches earth = 1.4 kW/m^2 ; Stefan-Boltzmann constant = $5.7 \times 10^{-8} \text{ W/m}^2\text{K}^4$.

(wasconsin)

Solution:

We assume that the surface of Neptune and the thermodynamics of its atmosphere are similar to those of the earth. The radiation flux on the earth's surface is

$$J_E = 4.18 \times 10^8 \text{ W/m}^2$$

The equilibrium condition on Neptune's surface gives

28

Hence

Problem #3 Solution on Thermodynamics & Statistical Mechanics

$$J_E = J_N = 4\sigma T_N^4$$

and we have

$$(1.5 \times 10^8)^2$$

$$(5.7 \times 10^{-8})^4 = 5.2 \text{ K}$$

$$= 5.2 \text{ K}$$

2. THE SECOND LAW AND ENTROPY (1031-1072)

1031

A steam turbine is operated with an intake temperature of 400°C , and an exhaust temperature of 150°C . What is the maximum amount of work the turbine can do for a given heat input Q ? Under what conditions is the maximum achieved?

(wisconsin)

Solution:

From the Clausius formula

we find the external work to be

Substituting $T_1 = 673 \text{ K}$ and $T_2 = 423 \text{ K}$ in the above we have

$$W = (1 - \frac{423}{673}) Q = 0.379 Q$$

As the equal sign in the Clausius formula is valid if and only if the cycle

is reversible, when and only when the steam turbine is a reversible engine can it achieve maximum work.

Thermodynamics 29

1034

A Carnot engine has a cycle as shown in Fig. 1.12. If W and W' represent work done by 1 mole of monatomic and diatomic gas, respectively, calculate W'/W .

$$W = (U_1 - U) - (U - U_2) = U_1 - U_2 = 2u$$

$$= NC(T_1 + T_2 - 2T) .$$

1036

Water powered machine. A self-contained machine only inputs two equal steady streams of hot and cold water at temperatures T_1 and T_2 . Its only output is a single high-speed jet of water. The heat capacity per unit mass of water, C , may be assumed to be independent of temperature. The machine is in a steady state and the kinetic energy in the incoming streams is negligible.

- (a) What is the speed of the jet in terms of T_1, T_2 and T , where T is the temperature of water in the jet?
- (b) What is the maximum possible speed of the jet?

Fig. 1.13.

33

Solution:

- (a) The heat intake per unit mass of water is

$$AQ [C(T_1 - T) - C(T - T_2)]/2 .$$

As the machine is in a steady state, $v^2/2 = AQ$, giving

$$u = JC(T_1 + T_2 - 2T) .$$

- (b) Since the entropy increase is always positive, i.e.,

1037

In the water behind a high power dam (110 m high) the temperature difference between surface and bottom may be 10°C . Compare the possible energy extraction from the thermal energy of a gram of water with that generated by allowing the water to flow over the dam through turbines in the conventional way.

(Col urn bia)

Solution:

The efficiency of a perfect engine is

The energy extracted from one gram of water is then

where Q is the heat extracted from one gram of water, C_u is the specific heat of one gram of water. Thus

34 Problem 8 / Solution 8 on Thermodynamics & Statistical Mechanics

If T_{high} can be taken as the room temperature, then

$$W = 1 \times 102/300 = 0.3 \text{ cal} .$$

The energy generated by allowing the water to flow over the dam is

$$W' = mgh = 1 \times 980 \times 100 \times 10^7$$

$$= 10^7 \text{ erg} = 0.24 \text{ cal} .$$

We can see that under ideal conditions $W' < W$. However, the efficiency of an actual engine is much less than that of a perfect engine.

Therefore, the method by which we generate energy from the water height difference is still more efficient.

1038

Consider an engine working in a reversible cycle and using an ideal gas with constant heat capacity c_p as the working substance. The cycle consists of two processes at constant pressure, joined by two adiabatics.

adiabatics

c

Fig. V.1.14.

- (a) Find the efficiency of this engine in terms of p_1, p_2 .
- (b) Which temperature of T_a, T_b, T_c, T_d is highest, and which is lowest?
- (c) Show that a Carnot engine with the same gas working between the highest and lowest temperatures has greater efficiency than this engine.

(Col urn baa)

Solution:

source of higher temperature is

(a) In the cycle, the energy the working substance absorbs from the **Thermodynamics 35**

The energy it gives to the source of lower temperature is $Q_g = c_v(T_c - T_d)$.

Thus

From the equation of state $pV = nRT$ and the adiabatic equations

$$p_2 V_2^\gamma = p_1 V_1^\gamma, \quad p_2 v_2 = p_1 v_1; ,$$

we have

(b) From the state equation, we know $T_b > T_c, T_c > T_d$; from the adiabatic equation, we know $T_b > T_c, T_c > T_d$; thus

1039

A building at absolute temperature T is heated by means of a heat pump which uses a river at absolute temperature T_0 as a source of heat. The heat pump has an ideal performance and consumes power W . The building loses heat at a rate $\alpha(T - T_0)$, where α is a constant.

(a) Show that the equilibrium temperature T , of the building is given **by**

$$T = T_0 + \frac{W}{\alpha} [1 + (1 + \frac{W}{\alpha T_0})^{\frac{1}{\gamma-1}}]$$

(b) Suppose that the heat pump is replaced by a simple heater which also consumes a constant power W and which converts this into heat with 100% efficiency. Show explicitly why this is less desirable than a heat pump.

(Columbia)

36 Problem d Solution on Thermodynamics d Statistical Mechanics

Solution:

(a) The rate of heat from the pump is

At equilibrium, $T = T$, and $Q = Q_c = \alpha(T_e - T_0)$. Thus

(b) In this case, the equilibrium condition is

$$W = Q_c (T_e - T_0) .$$

Thus

$$W$$

$$T_e = T_0 + \frac{W}{\alpha}$$

q

Therefore it is less desirable than a heat pump.

1040

A room at temperature T_2 loses heat to the outside at temperature T_1 at a rate $A(T_2 - T_1)$. It is warmed by a heat pump operated as a Carnot cycle between T_1 and T_2 . The power supplied by the heat pump is dW/dt .

(a) What is the maximum rate dQ_m/dt at which the heat pump can deliver heat to the room? What is the gain dQ_m/dW ? Evaluate the gain for $t_1 = 2^\circ\text{C}, t_2 = 27^\circ\text{C}$.

(b) Derive an expression for the equilibrium temperature of the room, **(UC, Berkeley)**

T_2 , in terms of T_1, A and dW/dt .

Solution:

(a) From $dQ_m \cdot (T_2 - T_1)/T_2 = dW$, we get

With $T_1 = 275\text{K}, T_2 = 300\text{K}$, we have $dQ_m/dW = 12$.

(b) When equilibrium is reached, one has

$$T_2 dW$$

$$A(T_2 - T_1) = - T_2 - T_1 dt'$$

Thermodynamics 37

giving

1041

A building at a temperature T (in K) is heated by an ideal heat pump which uses the atmosphere at $T_0(K)$ as heat source. The pump consumes power W and the building loses heat at a rate $a(T - T_0)$. What is the equilibrium temperature of the building?

(MIT)

Solution:

Let T_e be the equilibrium temperature. Heat is given out by the pump at the rate $Q_I = W/\tau$, where $\tau = 1 - T_0/T_e$. At equilibrium $Q_I = a(T - T_0)$, so that

$$W = -a(T_e - T_0) \tau,$$

T_e

from which we get

$$T_e = T_0 + \frac{W}{a} \frac{1}{T_e - T_0}.$$

2a

1042

Let M represent a certain mass of coal which we assume will deliver 100 joules of heat when burned - whether in a house, delivered to the radiators or in a power plant, delivered at 1000°C . Assume the plant is ideal (no waste in turbines or generators) discharging its heat at 30°C to a river. How much heat will M , burned at the plant to generate electricity, provide for the house when the electricity is:

- delivered to residential resistance-heating radiators?
- delivered to a residential heat pump (again assumed ideal) boosting heat from a reservoir at 0°C into a hot-air system at 300°C ?

(Wisconsin)

38 Problem E/ Solution on Thermodynamics E/ Statistical Mechanics

Solution:

When M is burned in the power plant, the work it provides is $= 76.2\text{J}$.

This is delivered in the form of electric energy.

- When it is delivered to residential resistance-heating radiators, it
- When the electricity is delivered to a residential heat pump, heat **flows** from a source of lower temperature to a system at higher temperature, the working efficiency being will transform completely into heat: $Q' = W = 76.2\text{J}$.

$$\eta = \frac{T_1 - T_2}{T_1} = \frac{273 - 30}{273} = 0.89$$

$T_1 - T_2$

Hence the heat provided for the house is

$$Q' = (1 + \eta)W = 770\text{J}.$$

1043

An air conditioner is a device used to cool the inside of a home. It is, in essence, a refrigerator in which mechanical work W is done and heat removed from the (cooler) inside and rejected to the (warmer) outside.

A home air conditioner operating on a reversible Carnot cycle between the inside, absolute temperature T_1 , and the outside, absolute temperature T_2 , $T_1 > T_2$, consumes P joules/sec from the power lines when operating continuously.

- In one second, the air conditioner absorbs Q_2 joules from the house and rejects Q_1 joules outdoors. Develop a formula for the efficiency ratio Q_2/P in terms of T_1 and T_2 .

(b) Heat leakage into the house follows Newton's law $Q = A(T_1 - T_2)$.

Develop a formula for T_2 in terms of T_1 , P , and A for continuous operation

of the **air** conditioner under constant outside temperature T_1 and uniform (in space) inside temperature T_2 .

(c) The air conditioner is controlled by the usual on-off thermostat and it is observed that when the thermostat set at **20°C** and an outside temperature at 30° , it operates **30%** of the time. Find the highest outside temperature, in $^\circ\text{C}$, for which it can maintain 20°C inside (use -273°C for absolute zero).

(d) In the winter, the cycle is reversed and the device becomes a heat pump which absorbs heat from outside and rejects heat into the house. Find the lowest outside temperature in $^\circ\text{C}$ for which it can maintain 20°C inside.

(CUSPEA)

(a) (b)

Fig. 1.15.

Solution:

(a) From the first and second thermodynamic laws, we have

$$Q_2 = P + Q_1 \quad Q_2/T_2 = Q_1/T_1$$

Hence

$$\frac{Q_2}{T_2} = \frac{Q_1}{T_1} + \frac{P}{T_2}$$

(b) At equilibrium, heat leakage into the house is equal to the heat transferred out from the house, i.e., $Q_2 = A(T_1 - T_2)$. We obtain, using the result in (a).

Hence

In view of the fact $T_2 < T_1$, the solution is

$$T_2 = T_1 \frac{A + 1/E}{A - 1/m}$$

40 Problem 1.15 Solutions on Thermodynamics & Statistical Mechanics

(c) When the air conditioner works **30%** of the time, we know from (b) When it operates continuously, we have

100 100

$$P = p_{\text{son}} \cdot 30 \cdot 239 = A \cdot \dots = 1.13774$$

With $T_2 = 20^\circ\text{C} = 293\text{K}$, we get

$$T_1 = T_2 + \dots = 293 + \dots$$

$$= 293 + 18.26 \text{ K} = 311.26^\circ\text{C}$$

(d) When the cycle is reversed in winter, we have $Q_2 = P + Q_1$ and

$-Q_2 = -Q_1$. At equilibrium, $Q_2 = A(T_2 - T_1)$ so that

$T_2 = T_1$

$$\text{Thus } T_1 = T_2 - \frac{K}{T_2} = 293 - \frac{(1.14 \times 293)^2}{2} = 275\text{K} = 2^\circ\text{C}$$

1044

Calculate the change of entropy involved in heating a gram-atomic weight of silver at constant volume from 0° to 30°C . The value of C_v over this temperature may be taken as a constant equal to **5.85 cal/deg.mole**.

(Wisconsin)

Solution:

The change of entropy is

$$\int_0^{30} \frac{C_v}{T} dT = 5.85 \ln \frac{303}{273}$$

$$273 \text{ a.s.} \quad \Delta S = nC \ln \frac{T_f}{T_i} = 5.851n = \mathbf{n \ 6 \ cg \ T \ T_i}$$

$$= 0.61 \text{ cal/K.}$$

Thermodynamics 41

1045

A body of constant heat capacity C , and a temperature T_i is put into contact with a reservoir at temperature T_f . Equilibrium between the body and the reservoir is established at constant pressure. Determine the total entropy change and prove that it is positive for either sign of $(T_f - T_i)/T_f$.

You may regard 1% - $T_i/T_f < 1$.

Solution:

$T_i = T_f$. The change of entropy of the body is

(was $C \ln$)

We assume $T_i \neq T_f$ (because the change of entropy must be zero when

The change of entropy of the heat source is

Therefore the total entropy change is

When $z > 0$ and $z \neq 1$, the function $f(z) = z^{-1} - \ln z > 0$. Therefore

1046

One kg of H₂O at 0°C is brought in contact with a heat reservoir at

(a) what is the change in entropy of the water?

(b) what is the change in entropy of the universe?

(c) how could you heat the water to 100°C so the change in entropy of 100°C. When the water has reached 100°C, the universe is zero?

(was $C \ln$)

42 Problem d Solution on Thermodynamics & statistical Mechanics

Solution:

The process is irreversible. In order to calculate the change of entropy of the water and of the whole system, we must construct a reversible process which has the same initial and final states as the process in this problem.

(a) We assume the process is a reversible process of constant pressure.

The change in entropy of the water is

r_{373}

We substitute $m = 1 \text{ kg}$, and $C_H = 4.18 \text{ J/g}$ into it, and find

$$\Delta S_w = 1305 \text{ J/K.}$$

(b) The change in entropy of the heat source is

$$\Delta S_h = -|Q|/T = -1000 \times 4.18 \times 100/373$$

$$= -11121 \text{ J/K.}$$

Therefore the change of entropy of the whole system is

(c) We can imagine infinitely many heat sources which have infinitesimal temperature difference between two adjacent sources from 0°C to 100°C. The water comes in contact with the infinitely many heat sources in turn in the order of increasing temperature. This process which allows the temperature of the water to increase from 0°C to 100°C is reversible; therefore $\Delta S = 0$.

1047

Compute the difference in entropy between 1 gram of nitrogen gas at a temperature of 20°C and under a pressure of 1 atm, and 1 gram of liquid nitrogen at a temperature -196°C, which is the boiling point of nitrogen, under the same pressure of 1 atm. The latent heat of vaporization of nitrogen is 47.6 cal/gm. Regard nitrogen as an ideal gas with molecular weight 28, and with a temperature-independent molar specific heat at constant

pressure equal to 7.0 cal/mol.K.

(UC, Berkeley)

Thermodynamics 43

Solution:

The number of moles of 1 g nitrogen is

$$n = 1/28 = 3.57 \times 10^{-2} \text{ mol.}$$

The entropy difference of an ideal gas at 20°C and at -196°C is

$$\Delta S' = nC_p \ln(T_1/T_2) = 0.33 \text{ cal/K,}$$

and the entropy change at phase transition is

$$\Delta S'' = nL/T_z = 0.64 \text{ cal/K.}$$

Therefore $\Delta S = \Delta S' + \Delta S'' = 0.97 \text{ cal/K.}$

1048

A Carnot engine is made to operate as a refrigerator. Explain in detail, with the aid of (a) a pressure-volume diagram, (b) an enthalpy-entropy diagram, all the processes which occur during a complete cycle or operation. This refrigerator freezes water at 0°C and heat from the working substance is discharged into a tank containing water maintained at 20°C. Determine the minimum amount of work required to freeze 3 kg of water.

(SVNY, Buffalo)

$$W = Q_2 \sim$$

$Q_2 = ML$ is the latent heat for $M = 3 \text{ kg}$ of water at $T = 0^\circ\text{C}$ to become ice. As

$$L = 3.35 \times 10^5 \text{ J/kg,}$$

we find $W = 73.4 \times 10^3 \text{ J.}$

1049

$n = 0.081 \text{ kmol}$ of He gas initially at 27°C and pressure = $2 \times 10^5 \text{ N/m}^2$ is taken over the path $A \rightarrow B \rightarrow C$. For He

$$C_p = 3R/2, C_v = 5R/2.$$

Assume the ideal gas law.

from $A \rightarrow B$?

(a) How much work does the gas do in expanding at constant pressure

(b) What is the change in thermal or internal energy of the helium

(c) How much heat is absorbed in going from $A \rightarrow B$?

(d) If $B \rightarrow C$ is adiabatic, what is the entropy change and what is the

from $A \rightarrow B$?
 final pressure?
 Solution:

(was γ)

(a) For $A \rightarrow B$, the external work is
 $W = PA(VB - VA) = 1.0 \times 10^5 \text{ J} .$

Thermodynamics 45

(b) For $A \rightarrow B$, the increase of the internal energy is

$$\Delta U = \gamma W = C_v PA(VB - VA)/R = 3W/2 = 1.5 \times 10^5 \text{ J} .$$

$2.1 \times 10^5 \text{ J}$

γ
 1.1

1.1 | 1.1

0 1.0 1.5 2.0

$v(\text{m}^3)$

Fig. 1.17.

(c) By the first law of thermodynamics, the heat absorbed during $A \rightarrow$

B is $W + \Delta U = 2.5 \times 10^5 \text{ J} .$

(d) For $B \rightarrow C$, the adiabatic process of a monatomic ideal gas satisfies the equation

$$pV^\gamma = \text{const.} , \text{ where } \gamma = C_p/C_v = 5/3 .$$

Thus $p \sim V^{-\gamma}$; $p = p_c$ and $p_c = (v_B/v_c)^\gamma p_B = 1.24 \times 10^5 \text{ N/m}^2$.

In the process of reversible adiabatic expansion, the change in entropy is $\Delta S = 0$. This is shown by the calculation in detail as follows:

$$\Delta S = nC_v \ln \frac{T_c}{T_b} + nR \ln \frac{V_c}{V_b}$$

$$= nC_v \ln \frac{T_c}{T_b} + nR \ln \frac{V_c}{V_b}$$

$$= nC_v \ln \frac{T_c}{T_b} + nR \ln \frac{V_c}{V_b}$$

$$= nC_v \ln \frac{T_c}{T_b} + nR \ln \frac{V_c}{V_b}$$

$$= nC_v \ln \frac{T_c}{T_b} + nR \ln \frac{V_c}{V_b}$$

$$= nC_v \ln \frac{T_c}{T_b} + nR \ln \frac{V_c}{V_b}$$

$$\Delta S = nC_v \ln \frac{T_c}{T_b} + nR \ln \frac{V_c}{V_b} = 0$$

$$= 0$$

A mole of an ideal gas undergoes a reversible isothermal expansion

46 Problem 17 Solution on Thermodynamics & Statistical Mechanics

from volume V_1 to $2V_1$.

(a) What is the change in entropy of the gas?

(b) What is the change in entropy of the universe?

Suppose the same expansion takes place as a free expansion:

(a) What is the change in entropy of the gas?

(b) What is the change in the entropy of the universe?

(was γ)

Solution:

the system is

(a) In the process of isothermal expansion, the external work done by

$$pdV = RT \int_{V_1}^{2V_1} \frac{1}{V} dV = RT \ln 2 .$$

Because the internal energy does not change in this process, the work is supplied by the heat absorbed from the external world. Thus the increase of entropy of the gas is

(b) The change in entropy of the heat source $\Delta S_2 = -\Delta S_1$, thus the total change in entropy of the universe is

If it is a free expansion, the internal energy of the system is constant. As its final state is the same as for the isothermal process, the change in entropy of the system is also the same. In this case, the state of the heat source does not change, neither does its entropy. Therefore the change in entropy of the universe is $\Delta S = R \ln 2$.

1051

N atoms of a perfect gas are contained in a cylinder with insulating walls, closed at one end by a piston. The initial volume is V_1 and the initial temperature T_1 .

Thermodynamics 47

(a) Find the change in temperature, pressure and entropy that would occur if the volume were suddenly increased to V_2 by withdrawing the piston.

(b) How rapidly must the piston be withdrawn for the above expressions to be valid?

(MIT)

$$\left[\frac{E_j}{kT} \right]_{1,2} = -$$

Fig. 1.18.

Solution:

(a) The gas does no work when the piston is withdrawn rapidly. Also, the walls are thermally insulating, so that the internal energy of the gas does not change, i.e., $dU = 0$. Since the internal energy of an ideal gas is only dependent upon temperature T , the change in temperature is 0, i.e., $T_2 = T_1$. As for the pressure, $p_2/p_1 = V_1/V_2$. The increase in entropy is

(b) The speed at which the piston is withdrawn must be far greater than the mean speed of the gas molecules, i.e., $u \gg \bar{v} = \left(\frac{8kT}{\pi m} \right)^{1/2}$.

1052

A cylinder contains a perfect gas in thermodynamic equilibrium at p, V, T, U (internal energy) and S (entropy). The cylinder is surrounded by a very large heat reservoir at the same temperature T . The cylinder walls and piston can be either perfect thermal conductors or perfect thermal insulators. The piston is moved to produce a small volume change ΔV . "Slow" or "fast" means that during the volume change the speed of the piston is very much less than, or very much greater than, molecular speeds at temperature T . For each of the five processes below show (on your answer sheet) whether the changes (after the reestablishment of equilibrium) in the other quantities have been positive, negative, or zero.

48 Problems & Solutions on Thermodynamics & Statistical Mechanics

+ ΔV

- ΔV

T

Fig. 1.19

1. $\Delta T = 0, \Delta U = 0, \Delta S$

1. (+ ΔV) (slow) (conduct)

2. (+ ΔV) (slow) (insulate)

3. (+ ΔV) (fast) (insulate)

4. (+ ΔV) (fast) (conduct)

5. (- ΔV) (fast) (conduct)

(wisconsin)

Solution:

(1) For isothermal expansion, $\Delta T = 0, \Delta U = 0$, and

$$\Delta S = R \ln \frac{V_2}{V_1} > 0, \Delta p = -P \Delta V < 0, \Delta U = 0$$

(2) For adiabatic expansion, $\Delta Q = 0$. Because the process proceeds very slowly it can be taken as a reversible process of quasistatic states, then $\Delta S = 0$. The adiabatic process satisfies $pV^\gamma = \text{const}$. While V increases, p decreases, i.e., $\Delta p < 0$; and the internal energy of the system decreases because it does work externally, thus $\Delta U < 0$, or $\Delta T < 0$.

(3) The process is equivalent to adiabatic free expansion of an ideal gas, thus $\Delta S > 0, \Delta U = 0, \Delta T = 0, \Delta p < 0$.

(4) The result is the same as that of isothermal free expansion, thus $\Delta T = 0, \Delta U = 0, \Delta S > 0, \Delta p < 0$.

(5) The result is the same as that of isothermal free compression, thus $\Delta T = 0, \Delta U = 0, \Delta S < 0, \Delta p > 0$.

The above are summarized in the table below

Thermodynamics 49
1053

A thermally insulated box is separated into two compartments (volumes V_1 and V_2) by a membrane. One of the compartments contains an ideal gas at temperature T ; the other is empty (vacuum). The membrane is suddenly removed, and the gas fills up the two compartments and reaches equilibrium.

- (a) What is the final temperature of the gas?
- (b) Show that the gas expansion process is irreversible.

(MIT)

Fig. 1.20.

Solution:

(a) Freely expanding gas does no external work and does not absorb heat. So the internal energy does not change, i.e., $dW = 0$. The internal energy of an ideal gas is only a function of temperature; as the temperature does not change in the process, $T_f = T$.

(b) Assuming a quasi-static process of isothermal expansion, we can calculate the change in entropy resulting from the free expansion. In the **50 Problem d Solution on Thermodynamics and Statistical Mechanics** process, we have $dS = pdV/T, pV = NkT$. Hence,

$$S_2 - S_1 = \int_{V_1}^{V_2} \frac{pdV}{T} = Nk \ln \frac{V_2}{V_1}$$

V_1

Thus the freely expanding process of the gas is irreversible.

1054

A thermally conducting, uniform and homogeneous bar of length L , cross section A , density ρ and specific heat at constant pressure c_p is brought to a nonuniform temperature distribution by contact at one end with a hot reservoir at a temperature T_H and at the other end with a cold reservoir at a temperature T_C . The bar is removed from the reservoirs, thermally insulated and kept at constant pressure. Show that the change in entropy of the bar is

$$\Delta S = \frac{c_p \rho A L}{T_C} \ln \frac{T_H}{T_C}$$

(SVNY, *Buflulo*)

Solution:

As the temperature gradient in the bar is $(T'-T)/L$, the temperature at the cross section at a distance x from the end at T , can be expressed by

$T_x = T + (T_H - T)x/L$. As the bar is adiabatically removed, we have

$$T_f = (T_H + T)/2$$

from which we obtain

$$\text{But } c_p = T(aS/aT),$$

$$rL \int_{T_i}^{T_f} \frac{1}{T} dT$$

$$T_f =$$

L

$$AS = c_p p A dx$$

where $C_p = c_p p A L$.

Thermodynamics 51

1055

A mixture of 0.1 mole of helium ($\gamma_1 = C_p/C_v = 5/3$) with 0.2 mole of nitrogen ($\gamma_2 = 7/5$), considered an ideal mixture of two ideal gases, is initially at 300K and occupies 4 litres. Show that the changes of temperature and pressure of the system which occur when the gas is compressed slowly and adiabatically can be described in terms of some intermediate value of γ . Calculate the magnitude of these changes when the volume is reduced by 1%.

(UC, *Berkeley*)

Solution:

The entropy change for an ideal gas is

$$\Delta S = nC_p \ln(T_f/T_i) + nR \ln(V_f/V_i),$$

where n is the mole number, i and f indicate initial and final states respectively.

As the process is adiabatic the total entropy change in the nitrogen

gas and helium gas must be zero, that is, $\Delta S_1 + \Delta S_2 = 0$. The expression

for ΔS then gives

where

Together with the equation of state for ideal gas, it gives

where

$$n_1 C_{p1} + n_2 C_{p2}$$

$$n_1 C_{v1} + n_2 C_{v2}$$

$$\gamma =$$

Helium is monatomic, so that $C_{p1} = 3R/2$, $C_{v1} = 5R/2$; nitrogen is diatomic,

so that $C_{p2} = 5R/2$, $C_{v2} = 7R/2$. Consequently, $\gamma = 1.46$.

When $V_f = 0.99 V_i$, we have

$$T_f = 1.006 T_i = 302 \text{ K},$$

$$p_f = 1.016 p_i = 1.016 nRT/V = 2.0 \times 10^5 \text{ N/m}^2$$

52 Problems in Statistical Mechanics d. Statistical Mechanics

1056

Consider two ways to mix two perfect gases. In the first, an adiabatically isolated container is divided into two chambers with a pure gas A in the left hand side and a pure gas B in the right. The mixing is accomplished by opening a hole in the dividing wall.

Cross section: 

Fig. 1.21 (a).

In the second case the chamber is divided by two rigid, perfectly selective membranes, the membrane on the left is perfectly permeable to gas A but impermeable to gas B . The membrane on the right is just the reverse.

The two membranes are connected by rods to the outside and the whole chamber is connected to a heat reservoir at temperature T . The gases can be mixed in this case by pulling left hand membrane to the left and the right hand one to the right.

A permeable B permeable

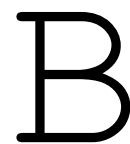

Cross section: 

Fig. 1.21 (b).

(a) Find the change in entropy of the container and its contents for second process.

(b) Find the change in entropy of the container and contents for the first process.

(c) What is the change in entropy of the heat reservoir in part (a)?

(CUSPEA)

Solution:

(a) Because the process is reversible, we have

Thermodynamics 53

where we have made use of the equation of state $pV = nRT$.

(b) Because energy is conserved and the internal energy of an ideal gas is related only to its temperature, the temperatures of the initial and final states are the same. The initial and final states of the gas in this case are identical with those in case (a). ΔS entropy is a function of state, ΔS is equal to that obtained in (a).

(c) $\Delta S_{\text{heat source}} = -\Delta S$, where ΔS is that given in (a).

1057

Consider a cylinder with a frictionless piston composed of a semipermeable membrane permeable to water only. Let the piston separate a volume V of N moles of pure water from a volume V' of a dilute salt (NaCl) solution. There are N' moles of water and n moles of the salt in the solution. The system is in contact with a heat reservoir at temperature T .

(a) Evaluate an expression for entropy of mixing in the salt solution.

(b) If the piston moves so that the amount of water in the salt solution

(c) Derive an expression for the pressure A across the semipermeable

(Prince ton)

(a) The entropy of mixing, i.e., the increase of entropy during mixing doubles, how much work is done?

membrane as a function of the volume of the salt solution.

Solution:

isothermally and isobarically is

$$N' n \Delta S = -N'R \ln \frac{N'}{N} + n - nR \ln \frac{n}{N} + n .$$

(b) The osmotic pressure of a dilute solution is

$$pV = nRT \text{ (Van't Hoff's law) .}$$

When the amount of water in the salt solution doubles, the **work** done is

$$W = \int_{V'}^{2V'} p dV = \int_{V'}^{2V'} \frac{nRT}{V} dV = nRT \ln 2.$$

V'

(c) $p = nRT/V'$. The osmotic pressure, i.e., the pressure difference across the membrane, is the net and effective pressure on the membrane.

54 Problems in Statistical Thermodynamics and Statistical Mechanics
1058

(a) In the big-bang theory of the universe, the radiation energy initially confined in a small region adiabatically expands in a spherically symmetric manner. The radiation cools down as it expands. Derive a relation between the temperature T and the radius R of the spherical volume of radiation, based purely on thermodynamic considerations.

(b) Find the total entropy of a photon gas as a function of its temperature T , volume V , and the constants k, h, c .

(SUNY, Buffalo)

Solution:

(a) The expansion can be treated as a quasi-static process. We then have $dU = TdS - pdV$. Making use of the adiabatic condition $dS = 0$ and the expression for radiation pressure $p = U/3V$, we obtain $dU/U = -dV/3V$; hence $U \propto V^{-1/3}$. The black body radiation energy density is $u = U/V = aT^4$, a being a constant. The above give $T^4 \propto V^{-4/3} \propto R^{-4}$, so that $T \propto R^{-1}$, i.e., $RT = \text{constant}$.

$$(b) dS = -dU + pdV = -Vdu + \frac{1}{3}duV = \frac{2}{3}duV$$

4

we obtain $S = \frac{4}{3}aT^3V$. By dimensional analysis we find $a = \frac{15}{4} \frac{k^4}{(hc)^3} \ln$.

fact, $a = \frac{15}{4} \frac{k^4}{(hc)^3}$ so that $S = \frac{4}{3}aT^3V$.

$\frac{15}{4} k^4$

$$\frac{15}{4} (hc)^{-3} \sim \frac{15}{4} (hc)^3$$

1059

(a) A system, maintained at constant volume, is brought in contact with a thermal reservoir at temperature T_f . If the initial temperature of

the system is T_i , calculate ΔS , change in the total entropy of the system + reservoir. You may assume that c_v , the specific heat of the system, is independent of temperature.

(b) Assume now that the change in system temperature is brought about through successive contacts with N reservoirs at temperature $T_i + \Delta T$, $T_i + 2\Delta T, \dots, T_i + (N-1)\Delta T, T_f$, where $N\Delta T = T_f - T_i$. Show that in the

limit $N \rightarrow \infty, \Delta T \rightarrow 0$ with $N\Delta T = T_f - T_i$ fixed, the change in entropy

of the system + reservoir is zero.

(c) Comment on the difference between (a) and (b) in the light of the second law of thermodynamics.

(SUNY, Buffalo)

55

Solution:

(a) The change in entropy of the system is

$$\Delta S = \int_{T_i}^{T_f} \frac{Mc}{T} dT$$

T_i

$$- Mc \ln \frac{T_f}{T_i}$$

The change in entropy of the heat source is

The total change in entropy is

$$\Delta S = \Delta S_{\text{system}} + \Delta S_{\text{source}} = Mc \ln \frac{T_f}{T_i} - Mc \ln \frac{T_f}{T_i} = 0$$

$N-1$

$$\Delta S = \lim_{N \rightarrow \infty} \sum_{n=1}^N \Delta S_n$$

$\Delta T = 0$

$\Delta T = \frac{T_f - T_i}{N}$

where

$\Delta T = \frac{T_f - T_i}{N}$

$$\Delta S_n = \frac{Mc}{T_i + n \Delta T} \Delta T$$

is the change in entropy of the $(n + 1)$ th contact. Thus

(c) The function $f(z) = z - \ln z - 1 > 0$ if $z > 0$ and $z \neq 1$. Thus

in (a) $\Delta S = Mc \ln(T_f/T_i) > 0$, that is, the entropy is increased. We know the process is irreversible from the second law of thermodynamics. In (b)

$\Delta S = 0$, the process is reversible.

1060

A material is brought from temperature T_i to temperature T_f by placing

it in contact with a series of N reservoirs at temperatures $T_i + \Delta T, T_i +$

56 Problems in Solution on Thermodynamics and Statistical Mechanics

$2\Delta T, \dots, T_i + (N-1)\Delta T = T_f$. Assuming that the heat capacity of the material,

C , is temperature independent, calculate the entropy change of the total system, material plus reservoirs. What is the entropy change in the limit

$N \rightarrow \infty$ for fixed $T_f - T_i$?

(Wisconsin)

Solution:

reservoir at temperature $T_i + (t + 1)\Delta T$.

equilibrium, the change of entropy of the material is

Consider the material at temperature $T_i + t\Delta T$ in contact with the

When they come to thermal

$$T_i + (t+1)\Delta T = C \ln \frac{T_i + (t+1)\Delta T}{T_i + t\Delta T}$$

$$\Delta S_1 = -C \ln \frac{T_i + (t+1)\Delta T}{T_i + t\Delta T}$$

$$\Delta S_1 = -C \ln \frac{T_i + (t+1)\Delta T}{T_i + t\Delta T}$$

The change in entropy of the heat reservoir is

$$\Delta S_2 = C \ln \frac{T_i + (t+1)\Delta T}{T_i + t\Delta T}$$

$$\Delta S_2 = C \ln \frac{T_i + (t+1)\Delta T}{T_i + t\Delta T}$$

$$\Delta S_2 = -C \ln \frac{T_i + (t+1)\Delta T}{T_i + t\Delta T}$$

The total change in entropy is

$$\Delta S_{\text{total}} = -C \ln \frac{T_i + (t+1)\Delta T}{T_i + t\Delta T} + C \ln \frac{T_i + (t+1)\Delta T}{T_i + t\Delta T} = 0$$

Therefore, after the material of initial temperature T_i has had contacts with

the series of reservoirs, the total change of entropy of the whole system is

$$\Delta S = C_A \sum_{i=1}^{N-1} \frac{dT_i}{T_i}$$

$$= C_A \int_{T_1}^{T_2} \frac{dT}{T}$$

When $N \rightarrow \infty$, or $\Delta T \rightarrow 0$, the above sum can be written as an integration, so that

Thermodynamics 57
1061

The specific heat of water is taken as 1 cal/g.K, independent of temperature, where 1 calorie = 4.18 joules.

- Define the specific heat of a substance at constant pressure in terms of such quantities as Q (heat), S (entropy), and T (temperature).
- One kg of water at 0°C is brought into sudden contact with a large heat reservoir at 100°C . When the water has reached 100°C , what has been the change in entropy of the water? Of the reservoir? Of the entire system consisting of both water and the heat reservoir?
- If the water had been heated from 0°C to 100°C by first bringing it into contact with a reservoir at 50°C and then another reservoir at 100°C , what would be the change in entropy of the entire system?
- Show how the water might be heated from 0°C to 100°C with (UC, Berkeley) negligible change in entropy of the entire system.

Solution: (a) $c_p = \left(\frac{dQ}{dT}\right)_p = \left(\frac{dS}{dT}\right)_p$

(b) The change in the entropy of the water is and the change in entropy of the reservoir is

$$\Delta S_w = \int_{273}^{373} \frac{1 \text{ cal/g.K}}{T} dT = 0.268 \text{ cal/g.K}$$

cal/g.K.

Thus $\Delta S_r = -0.268 \text{ cal/g.K}$.

(c) In this process, the change in entropy of the water is still $\Delta S_w = 0.312 \text{ cal/g.K}$, while that of the reservoir is

$$\Delta S_r = -1 \times \ln\left(\frac{373}{273}\right) - 1 \times \ln\left(\frac{373}{300}\right)$$

$$= -1 \times \ln\left(\frac{373}{273}\right) - 1 \times \ln\left(\frac{373}{300}\right)$$

$$= -0.289 \text{ cal/g.K}$$

So that $\Delta S_{\text{total}} = \Delta S_w + \Delta S_r = 0.023 \text{ cal/g.K}$.

(d) Divide the range of temperature $0^\circ\text{C} - 100^\circ\text{C}$ into N equal parts, with $N \gg 1$.

58 Problems 8 S d u t i o n Thermodynamics 8 Statistical Mechanics

At every temperature point, there exists a large heat reservoir. Let the water come into contact with them successively from low temperature to high temperature, to make the process of thermal contact quasi-static. Then $\Delta S = 0$ at every step and consequently for the entire process.

1062

Two finite, identical, solid bodies of constant total heat capacity per body, C , are used as heat sources to drive heat engine. Their initial temperatures are T_1 and T_2 respectively. Find the maximum work obtainable from the system.

Solution:

As energy is conserved, the work obtainable is $W = C(T_1 + T_2 - 2T_f)$, where T_f is the final temperature of the system. From the second law of thermodynamics, we have

(MIT)
 $T_f T_r$
 $T_l T_z$

$\Delta S = C \ln T_f + C \ln T_r - 2C \ln T_l > 0$, so that $T_f > T_l$.

Hence $W_{min} = C(T_l + T_2 - 2T_m)$.

1063

A rigid box containing one mole of air at temperature T_0 (in K) is initially in thermal contact with an "infinite" heat-capacity reservoir" at the same temperature T_0 . The box is removed from the reservoir and a cyclic engine is used to take some heat from the reservoir and put some into the air in the box. What is the minimum amount of work from T_0 to T_1 ? Express W in terms of T_0 , T_1 and the gas constant R , and state units. Ignore vibrational degrees-of-freedom in the air molecules and the heat capacity of the container. Would inclusion of vibrational degrees-of-freedom increase or reduce the value of W ?

(Columbia)

Solution:

"infinite heat-capacity reservoir", we get

As $Q = W + \Delta U_{air} = C(T_1 - T_0)$, where Q is the heat absorbed from the

reservoir. $\Delta S = \frac{Q}{T_0} + C \ln(T_1/T_0)$.

Thermodynamics 59

Hence

$W = C(T_1 - T_0) - C T_0 \ln(T_1/T_0) = W_{min}$.

With the inclusion of vibrational degrees-of-freedom, W_{min} increases as C increases.

1064

A reversible heat engine operates between two reservoirs, T_1 and T_2 ($T_2 > T_1$). T_1 can be considered to have infinite mass, i.e., T_1 remains constant. However the warmer reservoir at T_2 consists of a finite amount of gas at constant volume (ν moles with a specific heat capacity C_V). After the heat engine has operated for some long period of time, the temperature T_2 is lowered to T_1 .

(a) What is the heat extracted from the warmer reservoir during this period?

(b) What is the change of entropy of the warmer reservoir during this period?

(c) How much work did the engine do during this period?

(Columbia)

Solution:

(a) $Q_{ab} = \nu C_V (T_2 - T_1)$.

$dQ = \nu C_V dT$

$T_2 \rightarrow T_1$

(b) Because $dS = \frac{dQ}{T} = \nu C_V \frac{dT}{T}$, $\Delta S = \nu C_V \ln \frac{T_1}{T_2}$.

$dW = dQ - dU = \nu C_V dT - \nu C_V dT = -\nu C_V dT$, therefore the work done by the engine is

$$W = \int_{T_2}^{T_1} \nu C_V dT = \nu C_V (T_2 - T_1) \quad (2)$$

1065

(b) What is the maximum amount of work obtainable from the engine?

(UC, Berkeley)

Solution:

(a) The increase in entropy of the total system is

Thus $T_3 = \sqrt{T_1 T_2}$, or $T_3 > \sqrt{T_1 T_2}$.

(b) The maximum amount of work can be obtained using a reversible
heat engine, for which $\Delta S = 0$.

$W_{\max} = C(T_1 - T_3) - c(T_2 - T_3) = c(T_1 - T_2) + c(T_2 - T_3) = c(T_1 - T_3)$

1067

(a) What is the efficiency for a reversible engine operating around
the indicated cycle, where T is temperature in K and S is the entropy in
joules/K?

T

Fig. 1.22.

(b) A mass M of a liquid at a temperature T_1 is mixed with an equal mass of the same liquid at a temperature T_2 . The system is thermally insulated. If c_p is the specific heat of the liquid, find the total entropy change. Show that the result is always positive.

(UC, Berkeley)

62 Problems €4 Solutions on Thermodynamics €4 Statistical Mechanics

Solution :

(a) In the cycle, the heat absorbed by the engine is

$$Q = \frac{400 + 300}{2}$$

2

$$Q = (1000 - 500) = 1.75 \times 10^5 \text{ J},$$

and the work it does is

$$\frac{400 - 300}{2}$$

2

$$W = (1000 - 500) = 2.5 \times 10^4 \text{ J}$$

Thus the efficiency is $\eta = W/Q = 14.3\%$.

for

(b) Obviously the equilibrium temperature is $T_3 = (T_1 + T_2)/2$. Therefore thus

Since $(T_1 + T_2)/2 \geq \sqrt{T_1 T_2}$, we have $\Delta S \geq 0$.

1068

(a) One mole of an ideal gas is carried from temperature T_1 and molar volume V_1 to T_2, V_2 . Show that the change in entropy is

$$\Delta S = C_v \ln \frac{T_2}{T_1} + R \ln \frac{V_2}{V_1}$$

$$\Delta S = C_v \ln \frac{T_2}{T_1} + R \ln \frac{V_2}{V_1}$$

$$\Delta S = C_v \ln \frac{T_2}{T_1} + R \ln \frac{V_2}{V_1}$$

(b) An ideal gas is expanded adiabatically from (p_1, V_1) to (p_2, V_2) .

Then it is compressed isobarically to (p_2, V_1) . Finally the pressure is

increased to p_1 at constant volume V_1 . Show that the efficiency of the cycle is

is

$$\eta = 1 - \gamma(V_2/V_1 - 1)/(p_1/p_2 - 1),$$

where $\gamma = C_p/C_v$.

(Columbia)

Solution:

11

(a) From $dS = -(dU + pdV)/T = -(C_v dT + pdV)/T$ and

$$pV = RT,$$

we obtain

$$\Delta S = C_v \ln \frac{T_2}{T_1} + R \ln \frac{V_2}{V_1}$$

$$\Delta S = C_v \ln \frac{T_2}{T_1} + R \ln \frac{V_2}{V_1}$$

$$\Delta S = C_v \ln \frac{T_2}{T_1} + R \ln \frac{V_2}{V_1}$$

(b) The cycle is shown in the Fig. 1.23.

Because AB is adiabatic and an ideal gas has the equations $pV = nkT$ and

$C_p = C_v + R$, we get

64 Problem d Solutions on Thermodynamic 8 Statistical Mechanics

During the CA part of the cycle the gas absorbs heat

$$Q = \int_{CA} TdS = C_v dT = CV(T_1 - T_2)$$

Hence, the efficiency of the engine is

1069

(1) Suppose you are given the following relation among the entropy S , volume V , internal energy U , and number of particles N of a thermodynamic system: $S = A[NVU]^{1/3}$, here A is a constant. Derive a relation among:

(a) U, N, V and T ;

(b) the pressure p, N, V , and T .

(c) What is the specific heat at constant volume c_v ?

(2) Now assume two identical bodies each consists solely of a material obeying the equation of state found in part (1). N and V are the same for both, and they are initially at temperatures T_1 and T_2 , respectively. They are to be used as a source of work by bringing them to a common final temperature T_f . This process is accomplished by the withdrawal of heat from the hotter body and the insertion of some fraction of this heat in the colder body, the remainder appearing as work.

(a) What is the range of possible final temperatures?

(b) What T_f corresponds to the maximum delivered work, and what is

You may consider both reversible and irreversible processes in answer-
(Prince ton)

this maximum amount of work?

ing these questions.

Thermodynamics 65

Solution:

(1)

$$U = A^3 N^3 V^3$$

$$A^3 N^3 V^3$$

(2) When no work is delivered, T_f will be maximum. Then

2

$$3 \ln \left(\frac{T_f}{T_1} \right) = \int_{T_1}^{T_f} \frac{c_v dT}{T} = -A(T_f^{1/3} - T_1^{1/3}),$$

2

3

$$Q_2 = \int_{T_2}^{T_f} \frac{c_v dT}{T} = -A(T_f^{1/3} - T_2^{1/3}).$$

Since $Q_1 + Q_2 = 0$, we have

The minimum of T corresponds to a reversible process; for which the change in entropy of the system is zero. As

$$AS_1 = \int_{T_1}^{T_f} \frac{c_v dT}{T} = 2A(T_f^{1/3} - T_1^{1/3}),$$

$$AS_2 = \int_{T_2}^{T_f} \frac{c_v dT}{T} = 2A(T_f^{1/3} - T_2^{1/3}).$$

r_{Tf}

and $dS + dS = 0$, we have

W_{rev} corresponds to $T_{f, in, i}$ i.e., the reversible heat engine has the maximum delivered work

1070

One kilogram of water is heated by an electrical resistor from 20°C to 99°C at constant (atmospheric) pressure. Estimate:

- The change in internal energy of the water.
- The entropy change of the water.
- The factor by which the number of accessible quantum states of
- The maximum mechanical work achievable by using this water as a heat reservoir to run an engine whose heat sink is at 20°C.

Solution:

- The change in internal energy of the water is $\Delta U = Mc\Delta T = 1000 \times 1 \times 79 = 7.9 \times 10^4$ cal.
- The change in entropy is

$$\Delta S = \int_{T_1}^{T_2} \frac{Mc}{T} dT = Mc \ln \frac{T_2}{T_1} = 239 \text{ cal/K,}$$

- From Boltzmann's relation $S = k \ln \Omega$, we get

$\ln \Omega$

$$\ln \Omega = \frac{S}{k} = \frac{239}{1.38 \times 10^{-23}} = \exp(7 \times 10^{25}).$$

- The maximum mechanical work available is $W = T_1 \Delta S = 9 \times 10^3$ cal.

Thermodynamics 67

where $Q(T, q)$ is the heat that the capacitor absorbs when it is charged from 0 to q while in contact with a heat source of constant temperature T .

3. THERMODYNAMIC FUNCTIONS AND EQUILIBRIUM CONDITIONS (1073-1105)

1073

For each of the following thermodynamic conditions, describe a system, or class of systems (the components or range of components, temperatures, etc.), which satisfies the condition. Confine yourself to classical, single

component, chemical systems of constant mass. U is the internal energy and S is the entropy of the system.

(a) $\left(\frac{\partial S}{\partial V}\right)_T = 0$

Solution:

(a) The classical ideal gas.

This requires $\alpha < 0$, i.e., the system has a negative coefficient of expansion at constant pressure.

$\alpha = 0$. This requires $C_p = \infty$. The system has two

T

P, C_p

coexistent phases.

(d) $\left(\frac{\partial T}{\partial V}\right)_P = 0$. This requires $\beta = 0$; $\left(\frac{\partial S}{\partial V}\right)_T = 0$.

V

It is a system whose coefficient of pressure at constant volume is zero.

(e) All systems of a single component and constant mass satisfy this Maxwell relation.

1074

$$S = nR \ln \frac{U}{u} + \dots$$

Consider an ideal gas whose entropy is given by

U

n

$$S = nR \ln \frac{U}{u} + \dots$$

where n = number of moles, R = universal gas constant, U = internal energy, V = volume, and u = constant.

(a) Calculate c_p and c_v , the specific heats at constant pressure and volume.

72 Problems and Solutions on Thermodynamics and Statistical Mechanics

(b) An old and drafty house is initially in equilibrium with its surroundings at 32°F . Three hours after turning on the furnace, the house is at a cozy 70°F . Assuming that the air in the house is described by the above equation, show how the energy density (energy/volume) of the air inside the house compares at the two temperatures.

(Columbia)

Solution:

(a) The temperature T is determined by the following equation:

$$\frac{1}{T} = \frac{1}{nR} \left(\frac{\partial S}{\partial U}\right)_V = \frac{1}{nR} \left(-\frac{1}{u}\right)$$

$$T = \left(\frac{\partial U}{\partial S}\right)_V = 2U/2$$

Therefore, the specific heat at constant volume is

$$c_v = \left(\frac{\partial U}{\partial T}\right)_V = 5nR/2$$

$v/2$

The specific heat at constant pressure is

v

$$c_p = c_v + nR = 7nR/2$$

$U/5n$

$$(b) \quad - \left(\frac{\partial U}{\partial T}\right)_P = -R$$

$v/2$

Using the equation of state of ideal gas $pV = nRT$, we have

$$U = 5/2 nRT - pV$$

Because the pressure of the atmosphere does not change at the two temperatures in the problem, neither does the energy density.

1075

A perfect gas may be defined as one whose equation of state is $pV = NkT$ and whose internal energy is only a function of temperature. For a perfect gas show that

(a) $c_p = c_v + k$, where c_p and c_v are the heat capacities (per molecule)

(b) The quantity pV^γ is constant during an adiabatic expansion. (At constant pressure and constant volume respectively.

sume that $\gamma = c_p/c_v$, is constant.)

(MIT)

Thermodynamics 73

Solution:

Let C_p and C_v be the principal molar specific heats.

(a) From $pV = NkT$ and $TdS = dU + pdV$, we find

$$C_p - C_v = T \left(\frac{\partial S}{\partial T}\right)_P - T \left(\frac{\partial S}{\partial T}\right)_V = Nk$$

p

Hence $C_p - C_v = k$.

$pV = NkT$, we have

(b) For an adiabatic process, $TdS = 0$ and hence $C_p dT = -pdV$. From

$$pdV + Vdp = Nk dT = (C_p - C_v)dT,$$

giving $\gamma pdV + Vdp = 0$, i.e.,

$$pV^\gamma = \text{const.}$$

1076

The difference between the specific heat at constant pressure and the specific heat at constant volume is nearly equal for all simple gases. What is the approximate numerical value of $c_p - c_v$? What is the physical reason for the difference between c_p and c_v ? Calculate the difference for an ideal gas.

Solution:

(Wisconsin)

$$c_p - c_v = \frac{1}{m} \left[\left(\frac{\partial U}{\partial T}\right)_P - \left(\frac{\partial U}{\partial T}\right)_V \right]$$

where m is the mass of the gas. From the functional relationship

we can find

$$(\%) , = (\frac{\circ}{\circ}) V (z) (T\%) ,$$

Utilizing Maxwell's relation $(g)T = (g)V$, the above formula becomes

$$VTa2 (*I$$

P m

74 Problems of Scutiom on Thermodynamics of Statistical Mechanics

where a is the coefficient of thermal expansion, and K is the coefficient of compression. For an ideal gas, $a = -$ and $K = -$, thus $cp - c_v = nR/m = RIM$. (M is the molecular weight of the gas).

The formula (*) relates the difference of two specific heats to the equation of state. For some materials, the specific heat at constant volume or constant pressure is not easily measured in experiments; it can be determined with formula (*) by measuring K and a . For a simple gas, its values of a and K are near to those of an ideal gas. Thus, the difference between the two specific heats is approximately RIM . The reason that $cp > c_v$ is that the gas expanding at constant pressure has to do work so that more heat is absorbed for this purpose.

The following measurements can be made on an elastic band:

(a) The change in temperature when the elastic band is stretched. (In case you have not tried this, hold the attached band with both hands, test the temperature by touching the band to your lips, stretch the band and **Thermodynamics 77**

check the temperature, relax the band and check the temperature once more).

(b) One end of the band is fixed, the other attached to weight W , and

(c) With the weight at rest OQ is added, and the equilibrium length L

Derive the equation by which you can predict the result of the last
(Princeton)

the frequency u of small vibrations is measured.

is observed to change by $6L$.

measurement from the results of the first two.

Solution:

When heat $6Q$ is added with the weight at rest, i.e., with the stress kept unchanged, we have $6S = 6Q/T$. Therefore,

The elastic coefficient of the band is $k = W (\sim KY) \sim / \sim$.

As $L - L_0 = W/k$, we get

$$\left(\frac{\%}{\circ}\right) dL_0 W dk = dT - kZ dT ,$$

Thus

where

1081

The tension F in an ideal elastic cylinder is given by the equation of state

78 Problems in Thermodynamics and Statistical Mechanics

where a is a constant, L_0 is the length at zero tension, and $L(T)$ is a function of temperature T only.

(a) The cylinder is stretched reversibly and isothermally from $L = L_0$ to $L = 2L_0$. Find the heat transferred to the cylinder, Q , in terms of a , L_0 and a_0 , the thermal expansion coefficient at zero tension, being $a_0 = \frac{1}{L_0} \frac{dL_0(T)}{dT}$.

$L_0(T) dT$.

(b) When the length is changed adiabatically, the temperature of the cylinder changes. Derive an expression for the elastocaloric coefficient, $(\frac{dT}{aL})_S$ where S is the entropy, in terms of a , T, L, L_0, a_0 , and C_L , the heat capacity at constant length.

(c) Determine whether C_L is a function of T alone, $C_L(T)$, or whether it must also depend on the length, $C_L(T, L)$, for this system.

Solution:

(MIT)

Let \mathcal{A} be the free energy. From $d\mathcal{A} = -SdT + FdL$, we get

Thus

and

$$-aTL_0$$

Fig. 1.26.

Thermodynamics 79

$$(a) Q = T [S(T, 2L_0) - S_0] = -aTL_0 (1 + \int_{L_0}^{2L_0} \frac{a_0}{L} dL).$$

$$a_2s = TaLaT$$

$L; L$

$$= -aT \left\{ 1 + \int_{L_0}^{2L_0} \frac{a_0}{L} dL \right\} = -aTL_0 \left(1 + \int_{L_0}^{2L_0} \frac{a_0}{L} dL \right), \quad Z_0 L_2 L_0$$

Thus $C_L = C_L(T, L)$.

Information: If a rubber band is stretched adiabatically, its temperature increases.

(a) If the rubber band is stretched isothermally, does its entropy in-

(b) If the rubber band is stretched adiabatically, does the internal energy increase, decrease, or stay the same?

energy increase, decrease, or stay the same?

Solution:

done on it is

(wis **co nsin**)

(a) We assume that when the rubber band is stretched by dx the work

$$dW = kx dx ,$$

where k , the elastic coefficient, is greater than 0. From the formula $dF =$

$$-SdT + kx dx, \text{ we can obtain the Maxwell relation: } \left(\frac{\partial T}{\partial x}\right)_S = -\left(\frac{\partial k}{\partial S}\right)_x = 0$$

Hence the entropy of the rubber band stays the same while it is stretched

isothermally. $\left(\frac{\partial E}{\partial S}\right)_x =$

(b) According to the formula $dU = TdS + kx dx$, we have

$kx > 0$, that is, its internal energy increases while it is stretched adiabatically.

80 Problems & Solutions in Thermodynamics & Statistical Mechanics
1083

The tension of a rubber band in equilibrium is given by

where $t =$ tension, $T =$ absolute temperature, $z =$ length of the band, $l_0 =$ length of the band when $t = 0$, $A =$ constant.

When z is the constant length l_0 , the thermal capacity $c_x(z, T)$ is observed to be a constant K .

(a) Find as functions of T and x : ..

$$\frac{\partial E}{\partial x}$$

(1) $\left(\frac{\partial E}{\partial x}\right)_T$ where $E =$ internal energy, (2)

$$\frac{\partial E}{\partial T}$$

$E(z, T)$, (5) $S(z, T)$, where $S =$ entropy.

(b) The band is stretched adiabatically from $z = l_0$ to $z = 1.5l_0$. Its (CUSPEA)

initial temperature was T_0 . What is its final temperature?

Solution:

Then as

(a) From the theory of thermodynamics, we know $dE = TdS + t dz$.

$$c_x = T \left(\frac{\partial c_x}{\partial T}\right)_x ,$$

we have

Generally, $E = E(z, T)$, and we have

$$\left(\frac{\partial E}{\partial z}\right)_T = t dz.$$

$$\text{i.e., } dE = c_x dT + t dz$$

On the other hand,

$$dS = -\frac{1}{T} (dE - t dz) = -\frac{c_x}{T} dT + \frac{t}{T} dz$$

Thermodynamics 81

we obtain

$$\frac{\partial E}{\partial T} = c_x + \frac{t}{T} \left(\frac{\partial E}{\partial z}\right)_T$$

$$\frac{\partial E}{\partial z} = T \left(\frac{\partial c_x}{\partial z}\right)_T + \frac{t}{T} \left(\frac{\partial E}{\partial z}\right)_T$$

From ---

$$\frac{\partial E}{\partial z} = T \left(\frac{\partial c_x}{\partial z}\right)_T + \frac{t}{T} \left(\frac{\partial E}{\partial z}\right)_T$$

$$\frac{\partial E}{\partial z} = T \left(\frac{\partial c_x}{\partial z}\right)_T + \frac{t}{T} \left(\frac{\partial E}{\partial z}\right)_T$$

Thus $\left(\frac{\partial E}{\partial z}\right)_T = t - T \left(\frac{\partial c_x}{\partial z}\right)_T$.

Substituting the expression for t , we have $\left(\frac{\partial E}{\partial z}\right)_T = 0$. It follows

that $(ac/az) = 0$. Integrating, we get

$$E(z, T) = E(T) = \int g dz + E(T_0)$$

$$= \int KdT + E(T_0) = K(T - T_0) + E(T_0)$$

From

$$dS = \frac{dE}{T} + \frac{pdz}{T}$$

T

we find after integration

$$S(z, T) = K \ln T - \frac{Kz}{T} + \text{const.}$$

(:l:)

(b) For an adiabatic process $dS = 0$ so that

After integration we have

$$= 0.292AZ_0$$

Hence $T = T_0 \exp(0.292AZ_0/K)$.

82 ProMema d Solutions on Thermodynamics d Statistial Mechanic8

1084

Consider a gas which undergoes an adiabatic expansion (throttling process) from a region of constant pressure p_i and initial volume V_i to a region with constant pressure p_f and final volume V_f (initial volume 0). Fig. 1.27.

(a) By considering the work done by the gas in the process, show that the initial and final enthalpies of the gas are equal.

(b) What can be said about the intermediate states of the system?

(c) Show for small pressure differences $\Delta p = p_f - p_i$ that the temperature difference between the two regions is given by $\Delta T = -(\alpha - 1)\Delta p$,

$$\frac{V}{c_v}$$

$$\text{where } \alpha = \frac{c_p}{c_v} \text{ and } c_p = \left(\frac{g}{v} \right) \frac{dV}{dT} \bigg|_p$$

(d) Using the above result, discuss the possibility of using the process to cool either an ideal gas, or a more realistic gas for which $p = RT/(V - b)$. Explain your result.

(SUNY, Buffalo)

Solution:

which is equal to a reduction of the internal energy:

(a) The work done by the gas in the throttling process is $p_f V_f - p_i V_i$,

$$U_i - U_f = p_f V_f - p_i V_i$$

Thus $U_i + p_i V_i = U_f + p_f V_f$, i.e., $H_i = H_f$.

(b) Because the process is quasi-static, the final and initial states can be any two intermediate states. Thus the conclusion is still valid for intermediate states.

(c) From $dH = TdS + Vdp = 0$ and

$$dS = \left(\frac{g}{p} \right) p dT + \left(\frac{\alpha}{T} \right) T d p = \frac{g}{p} dT - c(g) dp,$$

Thermodynamics a3

we obtain

Thus for a small pressure difference Δp , we have approximately

(d) For an ideal gas, we have $pV = NRT$ and $\alpha = 1/T$. Hence

$$\Delta T = V(TQ - 1)\Delta p/c, = 0.$$

As $\Delta T = 0$ this process cannot be used to cool ideal gases. For a realistic gas for which $p = RT/(V - b)$, $\alpha = R/Vp$ and $V(\alpha T - 1) = -b$. Hence

$\Delta T = -b\Delta p/c$. As $\Delta p < 0$ for a throttling process, $\Delta T > 0$, such a gas cannot be cooled by this process either.

1085

(a) Using the equation of state $pV = NRT$ and the specific heat per mole $C_v = 3R/2$ for a monatomic ideal gas, find its Helmholtz free energy F as a function of number of moles N , V , and T .

(b) Consider a cylinder separated into two parts by an adiabatic, impermeable piston. Compartments a and b each contains one mole of a monatomic ideal gas, and their initial volumes are $V_{ai} = 10$ litres and $V_{bi} = 1$ litre, respectively. The cylinder, whose walls allow heat transfer only, is immersed in a large bath at 0°C . The piston is now moved reversibly so that the final volumes are $V_{af} = 6$ and $V_{bf} = 5$ litres. How much work is delivered by (or to) the system?

(Princeton)

(a) For an ideal gas, we have $dU = NC_v dT$ and $U = NC_v T + U_0$,

Solution:

where U_0 is the internal energy of the system when $T = 0$. As

$$dS = -NC_v dT + p dV, T$$

$$S = 3/2 N R \ln T + N R \ln V + S_0,$$

2

14 Problems in Thermodynamics and Statistical Mechanics

where S_0 is a constant. Assuming the entropy of the system is S_0 when $T = T_0$, $V = V_0$ we have

$$S = 3/2 NR \ln T + NR \ln V + S_0$$

$$2 T_0 V_0$$

where $F_0 = U_0 - T_0 S_0$.

(b) The process described is isothermal. When $dT = 0$, $dF = -pdV$.

The work delivered by the system is

1086

A Van der Waal's gas has the equation of state

(a) Discuss the physical origin of the parameters a and b . Why is the correction to p inversely proportional to V^2 ?

(b) The gas undergoes an isothermal expansion from volume V_1 to

(c) From the information given can you calculate the change in internal volume V_2 . Calculate the change in the Helmholtz free energy. energy? Discuss your answer.

(Wisconsin)

Solution:

(a) On the basis of the equation of state of an ideal gas, we introduce the constant b when considering the volume of a real gas to allow for the finite volumes of the molecules and we introduce the constant a to allow for the mutual attraction between molecules of the gas. Now we discuss why the pressure correction term is inversely proportional to V^2 .

Thermodynamics 86

Each of the molecules of the gas has a certain interaction region. For the molecules near the center of the volume, the forces on them are isotropic because of the uniform distribution of molecules around them. For the molecules near the walls (the distances from which are smaller than the

interaction distance of molecules), they will have a net attractive force directing inwards because the distribution of molecules there is not uniform. Thus the pressure on the wall must have a correction Δp . If Δk denotes the decrease of a molecule's momentum perpendicular to the wall due to the net inward attractive force, these $\Delta p = (\text{The number of molecules colliding with unit area of the wall in unit time}) \sim 2 A k A$. Δk is obviously proportional to the attractive force, the force is proportional to the number of molecules in unit volume, n , i.e., $\Delta k \propto n$, and the number of molecules colliding with unit area of the wall in unit time is proportional to n too, we have

$$\Delta p \propto n^2 \propto 1/V^2 .$$

(b) The equation of state can be written as

$$p = \frac{kT}{V - b}$$

$$p = \frac{kT}{V - b}$$

In the isothermal process, the change of the Helmholtz free energy is

$$pdV = -kT \frac{dV}{V - b}$$

$$= -kT \ln \left(\frac{V - b}{V_2 - b} \right)$$

(c) We can calculate the change of internal energy in the terms of T and V :

For the isothermal process, we have

$$dU = \left(\frac{\partial U}{\partial V} \right)_T dV$$

The theory of thermodynamics gives

$$\left(\frac{\partial U}{\partial V} \right)_T = T \left(\frac{\partial p}{\partial T} \right)_V - p$$

Use of the equation of state then gives

$$dU = -p dV$$

Problems 4 Solution on Thermodynamics and Statistical Mechanics

Integrating, we find

$$1087$$

A 100-ohm resistor is held at a constant temperature of 300 K. A current of 10 amperes is passed through the resistor for 300 sec.

- What is the change in the entropy of the resistor?
- What is the change in the entropy of the universe?
- What is the change in the internal energy of the universe?
- What is the change in the Helmholtz free-energy of the universe?

(Wisconsin)

Solution:

(a) As the temperature of the resistor is constant, its state does not change. The entropy is a function of state. Hence the change in the entropy of the resistor is zero: $\Delta S_1 = 0$.

(b) The heat that flows from the resistor to the external world (a heat source of constant temperature) is

$$PRt = 3 \times 10^6 \text{ J}$$

The increase of entropy of the heat source is $\Delta S_2 = 3 \times 10^6 / 300 = 10^4 \text{ J/K}$.

Thus the total change of entropy is $\Delta S = \Delta S_1 + \Delta S_2 = 10^4 \text{ J/K}$.

(c) The increase of the internal energy of the universe is

$$\Delta U = 3 \times 10^6 \text{ J}$$

(d) The increase of the free energy of the universe is

$$\Delta F = \Delta U - T \Delta S = 0.$$

Thermodynamics 87

Blackbody radiation.

(a) Derive the Maxwell relation

(b) From his electromagnetic theory Maxwell found that the pressure p from an isotropic radiation field is equal to $-\frac{1}{3}$ the energy density $u(T)$: where V is the volume of the cavity. Using the first and second laws of thermodynamics together with the result obtained in part (a) show that u obeys the equation

1

3

1

3 3v

$$p = -\frac{1}{3} u(T)$$

$$1 \frac{du}{dT}$$

3 dT 3

$$u = -T^2 \frac{du}{dT} - u$$

(c) Solve this equation and obtain Stefan's law relating u and T .

(was constant)

Solution:

(a) From the equation of thermodynamics $dF = -SdT - pdV$, we know

$$-S = \left(\frac{\partial F}{\partial T} \right)_V = -p = \left(\frac{\partial F}{\partial V} \right)_T$$

we get

$$\text{Noting } dF = -SdT - pdV$$

$$d(uV) = T du + u dV$$

(b) The total energy of the radiation field is $U(T, V) = u(T)V$. Substituting it into the second law of thermodynamics:

$$\left(\frac{\partial U}{\partial T} \right)_V = T \left(\frac{\partial U}{\partial V} \right)_T - P = T \left(\frac{\partial U}{\partial V} \right)_T - P$$

$$T du = -P dV$$

3 dT 3

$$\text{we find } u = -\frac{P}{T} - u$$

du

(c) The above formula can be rewritten as $T \frac{du}{u} = -4 \frac{dT}{T}$, whose solution

dT

is $u = aT^4$, where a is the constant of integration. This is the famous Stefan's law of radiation for a black body.

88 Problems in Statistical Mechanics

1089

A magnetic system of spins is at thermodynamic equilibrium at temperature T . Let μ be the magnetic moment of each spin; and let M be the mean magnetization per spin, so $-\mu < M < \mu$. The free energy per spin, for specified magnetization M , is $F(M)$.

(1) Compute the magnetization M as a function of external magnetic field strength B , given that

where X is a constant.

(2) Suppose, instead, that someone gives you

$$F(M) = A(M/P)^4 - (M/d)^2$$

you should respond that this is unacceptable - this expression violates a fundamental convexity principle of thermodynamics. (a) State the principle. (b) Check it against the above expression. (c) Discuss, by at least one example, what would go wrong with thermodynamics if the principle is not satisfied.

(Princeton)

Solution:

(1) From $dF = -SdT + HdM$, we have

Hence

M

$$\frac{dF}{dM} = H$$

$$-M^{-5} = -1.$$

LC 2

1

F a ,

Thermodynamics 89

(2) (a) The convexity principle of free energy says that free energy is a concave function of T while it is a convex function of M , and if exists then $(\partial^2 F / \partial T^2) < 0$.

$$\left(\frac{\partial^2 F}{\partial T^2} \right) < 0,$$

(b) Supposing $F(M) = X \left[\frac{M}{T} \right]^4 - (f)'$, we have

$2X \frac{M^2}{T^4}$

$(\partial^2 F / \partial T^2) < 0$

$$\left(\frac{\partial^2 F}{\partial T^2} \right) = -12XT < 0,$$

M^2 / T^4

When $| -12XT | < 0$, $(\partial^2 F / \partial T^2) < 0$, i.e., F is not convex.

c1 x

(c) If the convexity principle is untenable, for example if

that is, $(\partial^2 F / \partial T^2) < 0$, then the entropy of the equilibrium state is a minimum

and the equilibrium state will be unstable.

In the reversible process at constant temperature and pressure, the decrease of Gibbs function of the system is equal to the difference between the total external work and the work the system does because of the change of volume. Thus

$$-Ag = EAq$$

Thermodynamics 91

or

$$-z (Ah - TAs) = EAq$$

If 1 mole of water forms, there must have been electric charges of 2F flowing in the circuit, i.e., $Aq = 2F$. Thus the e.m.f. is

As given, $S_o = 201$ J/mol.K, $S_H = 128$ J/mol K,

$SW = 66.7$ J/mol.K, $z_o = -17200$ J/mol

$hH = 8100$ J/mol, $hw = -269300$ J/mol, and $T = 298$ K,

We have $\epsilon = 1.23$ V.

1093

It is found for a simple magnetic system that if the temperature T is

held constant and the magnetic field H is changed to $H + \Delta H$, the entropy S changes by an amount ΔS ,

where C is a constant characteristic of the system. From this information

determine how the magnetization M depends on the temperature and

sketch a plot of M versus T for small H .

(wisconsin in)

Solution:

We are given that $\left(\frac{\partial G}{\partial T}\right)_H = -CH$

From $dG = -SdT - MdH$, we have

, CH that is $M = -\frac{CH}{T}$

Thus $\left(\frac{\partial Z}{\partial H}\right)_T = -\frac{CH}{T^2}$

$H T^2$

92 Problem, 8 Solutions on Thermodynamics & Statistical Mechanics

The diagram of M vs T is shown in Fig. 1.28.

Fig. 1.28.

1094

A certain magnetic salt is found to obey Curie's law, and to have a heat capacity per unit volume (at constant magnetic field) inversely proportional

to the square of the absolute temperature, i.e., $\chi = b/T$, $c_H = aV/T^2$,

where $or = b + aH^2$, a and b being constants, and χ is the susceptibility.

A sample of this salt at temperature T_1 is placed in a magnetic field of strength H . The sample is adiabatically demagnetised by slowly reducing the strength of the field to zero. What is the final temperature, T_2 , of the salt?

(Columbia)

Solution:

This process can be taken as reversible adiabatic. Then

$$dS = \left(\frac{\partial S}{\partial T}\right)_H dT + \left(\frac{\partial S}{\partial H}\right)_T dH = 0.$$

from $CH = T \left(\frac{\partial G}{\partial H}\right)_T$ and $dG = -SdT - pMVdH$, we can write

$$\left(\frac{\partial S}{\partial T}\right)_H = \frac{1}{T} \left(\frac{\partial G}{\partial T}\right)_H = -\frac{CH}{T^2}$$

$$\left(\frac{\partial S}{\partial H}\right)_T = -\frac{C}{T} \left(\frac{\partial G}{\partial H}\right)_T = -\frac{C}{T} \left(-\frac{CH}{T}\right) = \frac{CH}{T^2}$$

1095

Explain the principles of cooling by adiabatic demagnetization. What factors limit the temperature obtained with this method?

(with constants in)

Solution:

The fundamental equation of the thermodynamics of a magnetic medium

is $dU = TdS + HdM$. The Gibbs function is $G = U - TS - HM$,

giving $dG = -SdT - MdH$. From the condition of complete differential and

and the definition of specific heat, $CH = T \left(\frac{\partial C_H}{\partial T} \right)$ we obtain

If we assume the magnetic medium satisfies Curie's law

C_V

T

$M = \frac{C}{T} H$,

and substitute it into the above formula, we have

We can see that if the magnetic field is decreased adiabatically, the temperature of the magnetic medium will decrease also. This is the principle of cooling by adiabatic demagnetization.

94 Problem 4 Solution on Thermodynamics 8 Statistical Mechanics

Adiabatic demagnetization can produce temperatures as low as 1 K to K,

the interactions between the paramagnetic ions cannot be neglected. The interactions are equivalent to a magnetic field. It thus limits the lowest temperature obtainable with this method.

K; but when the temperature is of the order of magnitude of

1096

A flask of conical shape (see figure) contains raw milk. The pressure is measured inside the flask at the bottom. After a sufficiently long time, the cream rises to the top and the milk settles to the bottom. [You may assume that the total volume of liquid remains the same.] Does the pressure increase, decrease, or remain the same? Explain.

Solution:

Let the volume of the cream be V_1 , its thickness be h_1 , and its density be ρ_1 ; and let the volume of the milk be V_2 , the thickness be h_2 and the density be ρ_2 . ρ stands for the density of raw milk.

1097

Assume the atmosphere to be an ideal gas of constant specific heat ratio $\gamma = C_p/C_v$. Also assume the acceleration due to gravity, g , to be constant over the range of the atmosphere. Let $z = 0$ at sea level, T_0, p_0, ρ_0 be the absolute temperature, pressure, and density of the gas at $z = 0$.

(a) Assuming that the thermodynamic variables of the gas are related

Thermodynamics 95

in the same way they would be for an adiabatic process, find $p(z)$ and $\rho(z)$.

(b) Show that for this case no atmosphere exists above a z_{max} given

by $z_{max} = \frac{2}{\gamma - 1} \left(\frac{p_0}{\rho_0 g} \right)$ where R is the universal gas constant per gram.

Solution:

7-1

(SUNY, Buffalo)

(a) When equilibrium is reached, we have

By using the adiabatic relation $p\rho^{-\gamma} = p_0\rho_0^{-\gamma}$, we obtain,

$$p = p_0 \left(\frac{\rho}{\rho_0} \right)^{\frac{\gamma}{\gamma-1}} = \rho^{\frac{\gamma}{\gamma-1}} \left(\frac{p_0}{\rho_0^{\frac{\gamma}{\gamma-1}}} \right)$$

7PO

With the help of the equation of state $p = \rho RT$, we find

and

$\frac{1}{\gamma(\gamma-1)}$

$$p(z) = p_0 \left[1 - \frac{\gamma z}{T_0} \right]^{\frac{1}{\gamma - 1}}$$

(b) In the region where no atmosphere exists, $p(z, \infty) = 0$. Thus

$$z = -\frac{p_0}{\rho g}$$

$$\frac{p_0}{\rho g}$$

1098

Consider simple models for the earth's atmosphere. Neglect winds, convection, etc, and neglect variation in gravity.

(a) Assume that the atmosphere is isothermal (at 0°C). Calculate an expression for the distribution of molecules with height. Estimate roughly the height below which half the molecules lie.

(b) Assume that the atmosphere is perfectly adiabatic. Show that the temperature then decreases linearly with height. Estimate this rate of temperature decrease (the so-called adiabatic lapse rate) for the earth.

(GUSPEA)

96 Problema 4 Solutions on Thermodynamics 4 Statistical Mechanics

Solution:

(a) The molecular number density at height h is denoted by $n(h)$. From the condition of mechanical equilibrium $dp = -nmgdh$ and the equation of state $p = nkT$, we find

$$-dp = nmg dh = \frac{p}{kT} dh$$

$$p = nkT$$

Thus $n(h) = n_0 \exp(-mgh/kT)$. Let $\int_0^h n(h) dh / \int_0^\infty n(h) dh = 1/2$, then

$$1$$

$$2$$

The average molecular weight of the atmosphere is 30. We have

$$8.31 \times 10^7 \times 273$$

$$30 \times 980$$

$$H = \frac{8.31 \times 10^7 \times 273}{30 \times 980} \text{ cm} = 8 \text{ km}$$

$$1 \text{ mg}$$

$p = nkT$ (b) $-dp = -nmg dh$ is still correct and the adiabatic process follows

$$p^{(\gamma-1)/\gamma} T = \text{const}$$

where $\gamma = 5/3$ (for diatomic molecules). Therefore $-dT \sim \gamma -$

$$\frac{dT}{T} = -\frac{m g}{k} dh$$

Integrating we get

$$kT$$

$$T - T_0 = -(\gamma - 1)mg(h - h_0)/\gamma k$$

Furthermore,

$$dT = -$$

$$-$$

$$mg \approx -0.1 \text{ K/m}$$

$$dh \approx k$$

1099

The atmosphere is often in a convective steady state at constant entropy, not constant temperature. In such equilibrium pV^γ is independent of altitude, where $\gamma = C_p/C_v$. Use the condition of hydrostatic equilibrium in a uniform gravitational field to find an expression for dT/dz , where z is the altitude.

(UC, Berkeley)

Thermodynamics 97

Solution:

In the atmosphere, when the gas moves, pressure equilibrium can be quickly established with the new surroundings, whereas the establishment

of temperature equilibrium is much slower. Thus, the process of formation of gas bulk can be regarded as adiabatic. Resulting from many times of mixing by convection, the temperature distribution of the atmosphere can be considered such that there is no temperature difference between the compressed or expanded gas bulk and its new surroundings. This is the so called "convective steady state at constant entropy". From $dp/dz = -nmg$ (where n is the molecular number density and z the altitude) and the equation of state of an ideal gas $p = nkT$, we get Together with the equation of adiabatic process

$T \rho^{-\gamma} = \text{const}$,
we find

$$\frac{dT}{dz} = -\frac{1}{\gamma} \frac{mg}{k}$$

It can be seen that the temperature decreases linearly. The temperature drops 1.0°C when the height increases by 100 metres.

1100

The gas group that is slowly and adiabatically arising and unrestricted near the ground cannot continuously rise; neither can it fall (the atmosphere almost does not convect). If the height z is small, the pressure and temperature of the atmosphere are respectively $p = p_0(1 - az)$ and $T = T_0(1 - \beta z)$, where p_0 and T_0 are respectively the pressure and temperature near the surface. Find a and β as functions of the temperature T_0 , gravitational acceleration near the surface, g , and the molecular weight M . Suppose that air consists of N_2 and O_2 , and that T_0 is low enough so that the molecule oscillations cannot be excited, but is high enough so that the molecule rotation can be treated by the classical theory.

(CUSPEA)

5 5

98 Problem 8 Solution on Thermodynamics & Statistical Mechanics

Solution:

Near the ground, we have

$$dp/dz = -\rho g$$

Dynamic considerations give $dp/dz = -\rho g$.

Thus $a = \rho g/p_0$, where ρ_0 is the density of air near the ground. Treating air as an ideal gas, we have

$$p_0 = RT_0/V_0 = RT_0\rho_0/M,$$

where R is the gas constant, V_0 is the volume and M the molecular weight

$$\left(\because \rho = \frac{p_0 M}{RT_0} \right) \text{ Thus we have } a = Mg/RT_0.$$

The slow rising of the gas group can be taken as a quasi-static process.

It has the same p and ρ as the atmosphere surrounding it. Thus the same is also true of the temperature T . In the adiabatic process,

$$p \rho^{-\gamma} = \text{const},$$

with

$$\gamma = C_p/C_v = (C_v + R)/C_v = 7/5.$$

Differentiating we have

$$\frac{dT}{T} - \gamma \frac{dp}{p} = 0$$

On the ground, $dT/T = -p dz$ and $dp/p = -a dz$. We substitute them into above formula and obtain

$$\rho = -\frac{1}{\gamma} a = -2a.$$

1101

Suppose that the earth's atmosphere is an ideal gas with molecular weight μ and that the gravitational field near the surface is uniform and produces an acceleration g .

(a) Show that the pressure p varies as

Thermodynamics 99

where z is the height above the surface, T is the temperature, and R is the gas constant.

(b) Suppose that the pressure decrease with height is due to adiabatic expansion. Show that

(c) Evaluate dT/dz for a pure N_2 atmosphere with $\gamma = 1.4$.

(d) Suppose the atmosphere is isothermal with temperature T . Find

(e) Suppose that at sea level, $p = p_0$ and $T = T_0$. Find $p(z)$ for an adiabatic atmosphere.

(Columbia)

Solution:

(a) Mechanical equilibrium gives $dp = -npgdz$, where n is the mole number of unit volume. Thus using the equation of state of an ideal gas $p = nRT$, we find

$$dp = -pgdz, \quad RT$$

or

$$dP = -\frac{1}{\gamma} \frac{dp}{p} dz$$

$$P = RT.$$

(b) The adiabatic process satisfies $T^\gamma p^{1-\gamma} = \text{const}$. Thus

(c) Comparing the result of (b) with that of (a), we deduce

$$\frac{dT}{dz}$$

For N_2 , $\gamma = 1.4$, we get $dT/dz = -4.7$ K/km.

(d) From (a) we find

100 Problems and Solutions on Thermodynamics €4 Statistical Mechanics

(e) From (a) and (b) we have

$$\text{Thus } pg = \frac{1}{\gamma} \frac{dp}{p} dz,$$

$$R T_0$$

$$p - \frac{1}{\gamma} \frac{dp}{p} dz = -\frac{p_0}{\gamma} dz,$$

Integrating, we get

This is, of course, valid only if

1102

A fully ionized gas containing a single species of ion with charge Z/e and atomic weight A is in equilibrium in a uniform gravitational field g . The gas is isothermal with temperature T and there is thermal equilibrium between the ions and the electrons. The gas has a low enough density that local interactions between the particles can be neglected.

(a) Show that to avoid charge separation there must be a uniform electric field E given by

where m_p and

(b) Show

m_e are the proton and electron masses respectively.

that the above equation is also valid if the plasma is not isothermal. (Hint: Treat each component i as an ideal gas subject to the equation of hydrostatic equilibrium

Thermodynamics 101

where p_i is the partial pressure of the i th component, n_i is its number density, and F_i is the total force per particle in the z direction.)

(c) The equation in (a) is also valid throughout the sun where \mathbf{E} and \mathbf{g} are now directed radially. Show that the charge on the sun is given approximately by

$$A GMm,$$

$$1 + Z \frac{eJ}{Q} \dots$$

where M is the mass of the sun.

(d) For the sun $M = 2 \times 10^{30}$ grams. If the composition of the sun were pure hydrogen, what would be Q in coulombs? Given this value of Q , is the approximation that there is no charge separation a good one?

Solution:

(a) Take an arbitrary point in the gravitational field as the zero potential point. The number density at this point is n and the height is taken opposite to the direction of \mathbf{g} . Suppose there exists a uniform electric field \mathbf{E} in the direction opposite to \mathbf{g} . The electron and ion distributions as functions of height are respectively

(MITI

$$n_e(h) = n_0 \exp[-(m_e g h + E_e h)/kT],$$

$$n_i(h) = n_0 \exp[-(A m_i g h - E_i h)/kT].$$

To avoid charge separation, the following condition must be satisfied:

$$n_i(h)/n_e(h) = n_{i0}/n_{e0}.$$

$$A m_i g - E_i h = m_e g + E_e h,$$

This gives

from which we get

$$(b) -dP_i = n_i(-A m_i g + Z_i e E),$$

dh

At equilibrium, the partial pressure for each type of particles (at the same height) should be the same. Thus

102 Problems in Statistical Mechanics

i.e.,

$$-A m_i g + Z_i e E = -m_e g - e E.$$

$$A m_i g - m_e g,$$

$$(1 + Z_i e E / m_i g) \text{ Hence } E = \dots$$

$$Q = 4\pi r^2 GM \rho$$

$$r^2 r g = r^2 r (c) AS E = \dots, \text{ we have}$$

$$GM A m_i - m_e GM A m_i,$$

$$Q/r^2 = -m^2$$

$$(1 + Z_i e E / m_i g) r^2 (1 + Z_i e E / m_i g).$$

$$GM A m_i,$$

$$\text{Hence } Q =$$

$$(1 + Z) 14.$$

(d) For hydrogen, one has $A = 1, Z = 1$, giving

$$GMm,$$

$$Q = 1.5 \times 10^{30} \text{ oc}.$$

1103

Consider a thermally isolated system consisting of two volumes, V and $2V$ of an ideal gas separated by a thermally conducting and movable partition.

Fig. 1.30

The temperatures and pressures are as shown. The partition is now allowed

to move without the gases mixing.

When equilibrium is established what is the change in the total internal energy? The total entropy?

What is the equilibrium temperature? Pressure?

(SUN Y, Buffalo)

Thermodynamic a 103

Solution:

Let the molar numbers of the gas in the two sides be n_1 and n_2 respectively.

From the equations $6pV = n_1RT$ and $pV = n_2RT$, we obtain

$n_1 = 6n_2$. As this is an isolated system of ideal gas, the final temperature is $T_f = T$ since both the initial temperatures are equal to T . The final pressure p_f is

$$p_f = (n_1 + n_2)RT/3V =$$

3

We calculate the change of the state function S by designing a quasi-static isothermal process. Then

$V_1^{n_1} V_2^{n_2} = 3V^{n_1+n_2}$

Since $V_1 + V_2 = 3V$ and $V_1^{n_1} V_2^{n_2} = 3V^{n_1+n_2}$, hence $n_2 = 7$

$$\Delta S = n_1 R \ln \frac{V_1}{V} + n_2 R \ln \frac{V_2}{V} = 7R \ln 2$$

1104

A thermally insulated cylinder, closed at both ends, is fitted with a frictionless heat-conducting piston which divides the cylinder into two parts.

Initially, the piston is clamped in the center, with 1 litre of air at 200 K and 2 atm pressure on one side and 1 litre of air at 300 K and 1 atm on the other side. The piston is released and the system reaches equilibrium in pressure and temperature, with the piston at a new position.

(a) Compute the final pressure and temperature.

(b) Compute the total increase in entropy.

Be sure to give all your reasoning.

(SUNY, Buffalo)

104 Problems in Statistical Mechanics

Solution:

(a) The particle numbers of the two parts do not change. Let these be N_1 and N_2 , the final pressure be p , and the final temperature be T . Taking air as an ideal gas, we have

$$p_1 V_1 = N_1 k T_1, \quad p_2 V_2 = N_2 k T_2,$$

where $p_1 = 2$ atm, $T_1 = 200$ K, $p_2 = 1$ atm, $T_2 = 300$ K, $V_1 = 1$ l.

The piston does not consume internal energy of the gas as it is frictionless, so that the total internal energy of the gas is conserved in view of the cylinder being adiabatical. Thus

$$N_1 p_1 k T_1 + N_2 p_2 k T_2 = p(N_1 + N_2) k T,$$

where ν is the degree of freedom of motion of an air molecule. Hence

$$p_1 T_1 + \frac{N_2}{N_1} p_2 T_2 = p T$$

$$N_1 = p_1 T_1 = 225 K$$

$$N_2 = \frac{p_2 T_2}{p_1 T_1} N_1 = 112.5$$

$$N_1 p_1 T_2 =$$

$$T =$$

By $V_1 + V_2 = 2V_0$, we find

and hence

$$(N_1 + N_2)$$

$$2V_0 p =$$

(b) Entropy is a state function independent of the process. To calculate the change of entropy by designing a quasi-static process, we denote the entropies of the two parts by S_1 and S_2 . Then

$$\Delta S = \Delta S_1 + \Delta S_2 =$$

Thermodynamics 105

where n_1 and n_2 are the molar numbers of the particles in the two parts, c_v is the molar specific heat at constant volume, and R is the gas constant.

Thus

3
2

Taking $c_v = \frac{5}{2}R$ as the temperature of the system is not high, we have

$$\Delta S = 0.4 \text{ J/cal.}$$

1105

A cylindrical container is initially separated by a clamped piston into two compartments of equal volume. The left compartment is filled with one mole of neon gas at a pressure of 4 atmospheres and the right with argon gas at one atmosphere. The gases may be considered as ideal. The whole system is initially at temperature $T = 300 \text{ K}$, and is thermally insulated from the outside world. The heat capacity of the cylinder-piston system is C (a constant).

piston /

argon

Fig. 1.31.

The piston is now unclamped and released to move freely without friction. Eventually, due to slight dissipation, it comes to rest in an equilibrium position. Calculate:

- (a) The new temperature of the system (the piston is thermally conductive).
- (b) The ratio of final neon to argon volumes.
- (c) The total entropy change of the system.
- (d) The additional entropy change which would be produced if the piston were removed.

106 Problems in Statistical Mechanics

- (e) If, in the initial state, the gas in the left compartment were a mole of argon instead of a mole of neon, which, if any, of the answers to (a), (b) and (c) would be different?

(UC, Berkeley)

Solution:

(a) The internal energy of an ideal gas is a function dependent only on temperature, so the internal energy of the total system does not change. Neither does the temperature. The new equilibrium temperature is 300 K.

(b) The volume ratio is the ratio of molecular numbers, and is also the ratio of initial pressures. Thus

$$\frac{V_1}{V_2} = \frac{p_2}{p_1} = \frac{1}{4} = \frac{n_2}{n_1}$$

where $n_2 = \frac{1}{4}$ is the mole number of the argon gas.

(c) The increase of entropy of the system is

$$\Delta S =$$

$$R \ln \frac{5}{4} + R \ln \frac{1}{4} = 2.0 \text{ J/K.}$$

2 2

$$= R \ln \frac{5}{4} + R \ln \frac{1}{4} = 2.0 \text{ J/K.}$$

$$- R \ln 4 -$$

(d) The additional entropy change is

$$\Delta S' = R \ln(1 + n_2) + n_2 R \ln$$

(e) If initially the gas on the left is a mole of argon, the answers to (a),

(b) and (c) will not change. As for (d), we now have $\Delta S' = 0$.

1106

Is the melting point of tungsten 350, 3500, 35,000, or 350,000°C?

(Columbia)

Solution:

The answer is 3500°C.

Thermodynamics 107

1107

Assuming that 1/20 eV is required to liberate a molecule from the surface of a certain liquid when $T = 300 \text{ K}$, what is the heat of vaporization in ergs/mole?

[$eV = 1.6 \times 10^{-19} \text{ erg}$]

(Wisconsin)

Solution:

The heat of vaporization is

1
20

$L_{\text{vapor}} = 1.6 \times 10^{-19} \times 6.023 \times 10^{23}$

$= 4.8 \times 10^4 \text{ ergs/mol.}$

1108

Twenty grams of ice at 0°C are dropped into a beaker containing 120 grams of water initially at 70°C. Find the final temperature of the mixture neglecting the heat capacity of the beaker. Heat of fusion of ice is 80 cal/g.

(Wisconsin)

Solution:

We assume the temperature of equilibrium to be T after mixing. Thus

We substitute $M_1 = 20 \text{ g}$, $M_2 = 120 \text{ g}$, $T_0 = 70^\circ\text{C}$, $L_{\text{fusion}} = 80 \text{ cal/g}$

and $C_{\text{p,water}} = 1 \text{ cal/g}$, and obtain the final temperature $T = 48.57^\circ\text{C}$.

1109

The entropy of water at atmospheric pressure and 100°C is 0.31 cal/g.deg, and the entropy of steam at the same temperature and pressure is 1.76 cal/g.deg.

(a) What is the heat of vaporization at this temperature?

(b) The enthalpy ($H = U + PV$) of steam under these conditions is 640 cal/g. Calculate the enthalpy of water under these conditions.

108 Problems in Thermodynamics and Statistical Mechanics

(c) Calculate the Gibbs functions ($G = H - TS$) of water and steam

(d) Prove that the Gibbs function does not change in a reversible

(UC, Berkeley)

under these conditions.

isothermal isobaric process.

Solution:

(a) Heat of vaporization is

$L = T\Delta S = 540 \text{ cal/g.}$

(b) From $dH = TdS + Vdp$, we get

$H_{\text{water}} - H_{\text{steam}} - T\Delta S = 100 \text{ cal/g.}$

(c) Since $G = H - TS$,

$G_{\text{water}} = H_{\text{water}} - TS_{\text{water}} = -16 \text{ cal/g}$

$G_{\text{steam}} = H_{\text{steam}} - TS_{\text{steam}} = -16 \text{ cal/g}$

(d) From $dG = -SdT + Vdp$, we see that in a reversible isothermal isobaric process, G does not change.

1110

Given 1.0 kg of water at 100°C and a very large block of ice at 0°C.

A reversible heat engine absorbs heat from the water and expels heat to the ice until work can no longer be extracted from the system. At the completion of the process:

- (a) What is the temperature of the water?
 (b) How much ice has been melted? (The heat of fusion of ice is 80 cal/g)
 (c) How much work has been done by the engine?
 (was **co win**)

Solution:

(a) Because the block of ice is very large, we can assume its temperature to be a constant. In the process the temperature of the water gradually decreases. When work can no longer be extracted from the system, the efficiency of the cycle is zero:

Thermodynamics 109

Therefore, the final temperature of the water is 0°C .

(b) The heat absorbed by the ice block is

$$Q_2 = \int_{T_1}^{T_2} [1 - r(t)] dQ = mC_v \Delta T = 8.5 \times 10^4 \text{ cal} .$$

This heat can melt ice to the amount of

$$M_{\text{ice}} = \frac{Q_2}{L_f} = 8.5 \times 10^4$$

cal / 80

$$= 1.06 \text{ kg} .$$

(c) The work done by the engine is

$$W = Q_1 - Q_2 = 1000 \times 100 \times 1 - 8.5 \times 10^4 = 1.5 \times 10^4 \text{ cal} .$$

1111

What is the smallest possible time necessary to freeze **2 kg** of water at 0°C if a **50** watt motor is available and the outside air (hot reservoir) is at **27°C**?

(**Wisconsin**)

Solution:

When **2 kg** of water at 0°C becomes ice, the heat released is

$$Q_2 = 1.44 \times 2 \times 10^3 / 18 = 1.6 \times 10^2 \text{ kcal} .$$

The highest efficiency of the motor is

Thus,

If we use the motor of $P = 50 \text{ W}$, the smallest necessary time is

110 Problems d Solution on Thermodynamics d Statistical Mechanics

With $T_1 = 300 \text{ K}$, $T_2 = 273 \text{ K}$, we find

$$= 1.3 \times 10^3 .$$

1112

Compute the theoretical minimum amount of mechanical work needed to freeze 1 kilogram of water, if the water and surroundings are initially at a temperature $T_0 = 25^\circ\text{C}$. The surroundings comprise the only large heat reservoir available.

($L_{\text{ice}} = 80 \text{ cal/g}$, $C_p = 1 \text{ cal/g} \cdot ^\circ\text{C}$) .

(**UC, Berkeley**)

Solution:

The minimum work can be divided into two parts W_1 and W_2 : W_1 is used to lower the water temperature from **25°C** to 0°C , and W_2 to transform water to ice. We find

$$W_1 = \int_{T_0}^{T_1} (T_0 - T) MC_p dT / T$$

ITo

$$= MC_p T_o \ln(T_o/T_r) - MC_f(T_o - T_f)$$

$$= 1.1 \times 10^3 \text{ cal}$$

$$W_2 = (T_o - T_f)LM/T_f = 7.3 \times 10^3 \text{ cal}$$

$$W = W_1 + W_2 = 8.4 \times 10^4 \text{ cal} = 3.5 \times 10^4 \text{ J}$$

111s

An ideal Carnot refrigerator (heat pump) freezes ice cubes at the rate of 5 g/s starting with water at the freezing point. Energy is given off to the room at 30°C. If the fusion energy of ice is 320 joules/gram,

- (a) At what rate is energy expelled to the room?
- (b) At what rate in kilowatts must electrical energy be supplied?
- (c) What is the coefficient of performance of this heat pump?

(wzs co nsin)

Thermodynam'cs 111

Solution:

(a) The rate that the refrigerator extracts heat from water is

$$Q_2 = 5 \times 320 = 1.6 \times 10^3 \text{ J/s}$$

The rate that the energy is expelled to the room is

$$Q_1 = Q_2 \frac{T_1}{T_2} = (303/273) \times 1.6 \times 10^3$$

J/s

$$= 1.78 \times 10^3 \text{ J/s}$$

(b) The necessary power supplied is

$$W = Q_1 - Q_2 = 0.18 \text{ kW}$$

(c) The coefficient of performance is

273

$$\frac{Q_2}{W} = \frac{1.6 \times 10^3}{0.18} = 9.1$$

$$\frac{T_2}{T_1 - T_2} = \frac{273}{30 - 273}$$

1114

A Carnot cycle is operated with liquid-gas interface. The vapor pressure is p_v , temperature T , volume V . The cycle is operated according to the following p - V diagram.

The cycle goes isothermally from 1 to 2, evaporating n moles of liquid.

This is followed by reversible cooling from 2 to 3, then there is an isothermal contraction from 3 to 4, recondensing n moles of liquid, and finally a reversible heating from 4 to 1, completes the cycle.

b'11111

"1 v2

(a) (b)

Fig. 1.32.

- (a) Observe that $V_2 - V_1 = V_g - V_l$ where V_g = volume of n moles of gas, V_l = volume of n moles of liquid. Calculate the efficiency in terms of

112 Problems & Solutions on Thermodynamics & Statistical Mechanics

A_p , $V_g - V_l$, and L_v = latent heat vaporization of a mole of liquid. Treat A_p and AT as small.

- (b) Recognizing that any two Carnot engines operating between T and $T - AT$ must have the same efficiency (why?) and that this efficiency is a

function of T and T alone, use the result of part (a) to obtain an expression for dp/dT in terms of V , $-Ve$, n , L , and T .

(CUSPEA)

Solution:

(a) The temperature T in the process from 1 to 2 is constant. Because the total volume does not change, $V_2 - V_1 = V_e - V_c$. The engine does work $p(V_2 - V_1)$ on the outside world in the cyclic process. The heat it absorbs is nL_e . Therefore, the efficiency is

(b) The efficiency of a reversible Carnot engine working between T and $T - \Delta T$ is

$$\eta = \frac{\Delta T}{T}$$

$$\eta = \frac{L_e}{nL_e}$$

$$\text{Thus } -dpV = nL_e$$

$$dT = T \frac{dp}{p}$$

1115

Many results based on the second law of thermodynamics may be obtained without use of the concepts of entropy or such functions. The method is to consider a (reversible) Carnot cycle involving heat absorption

Q at $(T + dT)$ and release at T such that external work ($W + dW$) is

done externally at $(T + dT)$ and $-W$ is done at T . Then $Q = \Delta U + W$, where ΔU is the increase in the internal energy of the system. One must go around the cycle so positive net work dW is performed externally, where $dW/dT = Q/T$. In the following problems devise such a cycle and prove the indicated relations.

(a) A liquid or solid has vapor pressure p in equilibrium with its vapor.

For 1 mole of vapor treated as a perfect gas, V (vapor) \gg V (solid or liquid), let l be the 1 mole heat of vaporization. Show that

$$d \ln p / dT = l / RT^2$$

Thermodynamics 113

(b) A liquid has surface energy density u and surface tension r .

dr

i) Show that $u = r - T \frac{dr}{dT}$.

dT

ii) If $r < 0$, and $dr/dT > 0$, will T increase or decrease for an

(Columbia)

Solution:

(a) Consider the following cycle: 1 mole of a liquid vaporizes at temperature

$T + dT$, pressure $p + dp$, the vapor expands adiabatically to T, p

and then condenses at T, p and finally it arrives adiabatically at its initial

state. Thus we have $Q = l$, $dW = (p + dp)V - pV = Vdp$, where V is the molar volume of the vapor, and

dr d^2r

adiabatic increase in area?

dT dT^2

$$-Vdp = \frac{4}{T} r$$

dT T

From the equation of state of an ideal gas $V = RT/p$, we have

$$d \ln p = \frac{1}{T} dT$$

$$dT = RT^2 \frac{dr}{r}$$

(b)(i) Consider the following cycle: A surface expands by one unit

area at $T + dT$, and then expands adiabatically to T , it contracts at T , and

comes back adiabatically to its initial state. For this cycle:

$$Q = u - r, \\ \frac{dr}{dT}$$

$$dW = -r(T) + T(dT) = -dT$$

Thus

or

$$-dr = -dT \\ \frac{dr}{dT} = 1$$

$$u = r - T$$

(ii) From conservation of energy, we have

$$d(Au) = dQ + r(T)dA,$$

where A is the surface area. As $dQ = 0$ in the adiabatic process,

$$(u - T)dA + Adu = 0,$$

1114 Problems and Solutions on Thermodynamics & Statistical Mechanics

or

From (i) we have

$$-du = -T \left(\frac{dA}{A} \right)$$

$$\frac{du}{dT}$$

With $dr/dT < 0$ and $d^2r/dp > 0$, the above equations give

Hence when the surface area increases adiabatically, its temperature increases also.

1116

The heat of melting of ice at 1 atmosphere pressure and 0°C is **1.4363 kcal/mol**. The density of ice under these conditions is **0.917 g/cm³** and the density of water is **0.9998 g/cm³**. If 1 mole of ice is melted under these conditions, what will be

(a) the work done?

(b) the change in internal energy?

(c) the change in entropy?

(*wisconsin*)

Solution:

(a) The work done is

$$= 1.013 \times 10^5 \times [(\&)-(\&)]$$

$$= -0.1657 \text{ J} = -0.034 \text{ cal}.$$

(b) The heat absorbed by the 1 mole of ice is equal to its heat of fusion:

$$Q = 1.4363 \times 10^3 \text{ cal}.$$

Thus the change in internal energy is

$$\Delta U = Q - W \text{ or } Q = 1.4363 \times 10^3 \text{ cal}$$

Thermodynamics

(c) The change in entropy is

1115

$$\Delta s = - = 1.4363 \times 10^3 = 5.26 \text{ cal/K} \cdot T \cdot 273$$

1117

10 kg of water at 20°C is converted to ice at -10°C by being put in contact with a reservoir at -10°C . This process takes place at constant pressure and the heat capacities at constant pressure of water and ice are 4180

and 2090 J/kg deg respectively. The heat of fusion of ice is 3.34×10^5 J/kg.

Calculate the change in entropy of the universe.

(was co nsin)

Solution:

The conversion of water at 20°C to ice at -10°C consists of the following processes. Water at 20°C → water at 0°C → ice at 0°C → ice at -10°C, where a and c are processes giving out heat with decreases of entropy and b is the process of condensation of water giving off the latent heat with a decrease of entropy also. As the processes take place at constant pressure, the changes of entropy are

b
273

$$\Delta S_1 = \int_{20}^0 \frac{mC_p dT}{T} = mC_p \ln \left(\frac{0}{20} \right) = -2955 \text{ J/K},$$

$$|\Delta S_2| = 10 \times 3.34 \times 10^5$$

$$\Delta S_2 = - \frac{10 \times 3.34 \times 10^5}{273} = -1.2234 \times 10^4 \text{ J/K},$$

To 273

263

$$\Delta S_3 = \frac{1}{273} \int_{0}^{-10} mC_p dT$$

$$2dT = mC_p \ln \left(\frac{-10}{0} \right) = -757 \text{ J/K}.$$

In the processes, the increase of entropy of the reservoir due to the absorbed heat is

$$10 \times (4180 \times 20 + 3.34 \times 10^5 + 2090 \times 10)$$

263

$$\Delta S_4 =$$

$$= 16673 \text{ J/K}.$$

Thus, the total change of entropy of the whole system is

$$\Delta S = \Delta S_1 + \Delta S_2 + \Delta S_3 + \Delta S_4 = 727 \text{ J/K}.$$

1118

Estimate the surface tension of a liquid whose heat of vaporization is (Columbia)

$$10^9 \text{ ergs/g (250 cal/g)}.$$

Solution:

The surface tension is the free energy of surface of unit area; therefore the surface tension is $\sigma = Qr\rho$, where Q is the heat of vaporization, r is the thickness of the surface ($r = 10^{-8} \text{ cm}$) and ρ is the liquid density ($\rho = 1 \text{ g/cm}^3$). Thus

1119

Define (a) critical point and (b) triple point in phase transformation.

Helium boils at 4.2 K under the atmospheric pressure $p = 760 \text{ mm}$ of mercury. What will be the boiling temperature of helium if p is reduced to 1 mm of mercury?

(UC, Berkely)

Solution:

Critical point is the terminal point of the vaporization line. It satisfies equations

$$(a p) T = 0, (3) = 0 . av_{av2}$$

Triple point is the coexistence point for solid, liquid, and gas. When

$p' = 1 \text{ mmHg}$, the boiling temperature is 2.4 K.

1122

(a) State Van der Waals' equation of state for a real gas.

(b) Give a physical interpretation of the equation.

(c) Express the constants in terms of the critical data T_c, V_c , and p_c .

(Wisconsin)

Solution:

(a) Van der Waal's equation of state for a real gas is

$$\left(p + \frac{3a}{V^2}\right)(V - b) = nRT.$$

(b) On the basis of the state equation for an ideal gas, we account for the intrinsic volumes of real gas molecules by introducing a constant b , and for the attractive forces among the molecules by introducing a pressure correction a/V^2 .

$(V - b) = nRT$, we have

$$p = \frac{nRT}{V - b} - \frac{3a}{V^2}$$

$$nRT \frac{dp}{dV} = -\frac{3a}{V^3}$$

so that

$$2nRT \frac{dp}{dV} = -\frac{6a}{V^4}$$

$$\left(\frac{dp}{dV}\right)_T = \frac{3a}{(V-b)^3 V^4}$$

Thermodynamica 119

$$dP = \frac{dp}{dV} dV$$

$$dV = \frac{dV}{dV}$$

At the critical point, we have $\left(\frac{dp}{dV}\right)_T = 0$, $\left(\frac{d^2p}{dV^2}\right)_T = 0$

$$\frac{3a}{V^4} = 0$$

$$\frac{6a}{V^5} = 0$$

= 0, so that

$$V_c = 3b, p_c = \frac{nRT_c}{2b} - \frac{3a}{4b^2}$$

$$\frac{3a}{4b^2} = \frac{3a}{4b^2}$$

namely, $a = 3p_c V_c^2, 2b = V_c/3$.

1123

The Van der Waals equation of state for one mole of an imperfect gas reads

$$\left(p + \frac{a}{V^2}\right)(V - b) = RT.$$

[Note: part (d) of this problem can be done independently of part (a) to (c).]

(a) Sketch several isotherms of the Van der Waals gas in the p - V plane (V along the horizontal axis, p along the vertical axis). Identify the critical point.

(b) Evaluate the dimensionless ratio pV/RT at the critical point.

(c) In a portion of the p - V plane below the critical point the liquid and gas phases can coexist. In this region the isotherms given by the Van der Waals equation are unphysical and must be modified. The physically correct isotherms in this region are lines of constant pressure, $p_0(T)$. Maxwell proposed that $p_0(T)$ should be chosen so that the area under the modified isotherm should equal the area under the original Van der Waals isotherm. Draw a modified isotherm and explain the idea behind Maxwell's construction.

Thermodynamics 121
1124

Determine the ratio (pV/RT) at the critical point for a gas which obeys the equation of state (Dieterici's equation)

$$p(V - b) = RT \exp(-a/RTV)$$

Give the numerical answer accurately to two significant figures.

(UC, Berkeley)

Solution:

The critical point satisfies

From the equation of state, we get

$$a(V - b)$$

$$\exp(-a/RTV) = \left[\frac{RTV}{a(V - b)^2} \right]^2$$

Consequently, $-1 = 0$.

Using this result, we get

$$a a$$

4b

Thus, $-2 = 0$. Then, $V = 26, RT = -RTV$

Substituting these back in the equation of state, we find $-PV = 0.27. RT$

1125

Find the relation between the equilibrium radius r , the potential Φ , and the excess of ambient pressure over internal pressure Δp of a charged soap bubble, assuming that surface tension can be neglected.

(Wi3 c o f 13 in)

122 Problems d Solutions on Thermodynamics d Statistical Mechanics

Solution:

We assume that the air inside the bubble is in α -phase, the air outside the bubble is in β -phase, and the soap bubble itself is in γ -phase. We can solve this problem using the principle of minimum free energy. If the temperature is constant, we have

$$\delta F = -p_a \delta V_a + p_b \delta V_b + \gamma \delta A + q \left(\frac{d}{dr} \right) \delta r,$$

4

3

where $V'' = -m36, V' = 4.rrr26r, \delta VP = -6 V''$.

The condition of minimum free energy demands

With $\Delta = q/r$, we have $\Delta p = -\gamma$

474

1126

Consider a spherical soap bubble made from a soap film of constant surface tension, a , and filled with air (assumed to be a perfect gas). Denote the ambient external pressure by p_0 and temperature by T .

(a) Find a relation between the equilibrium radius r of the soap bubble

(b) Solve the relation of part (a) for the radius r in the limit that the and the mass of air inside it.

bubble is "large". Define precisely what is meant by "large".

WIT)

Solution:

(a) Let dA be an infinitesimal area of soap bubble surface, p_1 and p_0 be the pressures inside and outside the soap bubble, and μ_1, μ_2 be their

chemical potentials. We have $dU = T dS - p_1 dV_1 - p_0 dV_2 + \mu_1 dN_1 + \mu_2 dN_2$.

Thermodynamic 123

From the condition of equilibrium: $dU = 0, dS = 0, p_1 = p_2, dV_1 = -dV_2$ and $d(N_1 + N_2) = 0$, we get $(p_1 - p_0)dV_1 = \mu_1 dN_1 + \mu_2 dN_2$,

where $\mu_1 - \mu_2 = -\Delta\mu$. Hence $\Delta\mu = 2\gamma/r$.

$\Delta\mu = -\Delta p$

m

is the molecular weight of air, we have

Since $p_1 V_1 = nRT$, where n is the mass of air inside the bubble, M

$4\pi M$

$$3RT/m = -\Delta\mu = 2\gamma/r \quad (F)$$

4rMpor3

3RT

(b) When $p_0 \gg 2\gamma/r$, i.e., $r \gg 2\gamma/p_0$, we have $r \approx$

1127

Derive the vapor pressure equation (Clausius-Clapeyron equation):

(UC, Berkeley)

$dp/dT = ?$

Solution:

Conservation of energy gives

where V_1 is the volume of the vapor, and V_2 is the volume of the liquid. In phase transition from liquid to vapor, chemical potential is invariant, i.e.,

$\mu_1 = \mu_2$, so that one has the vapor pressure equation:

where L is the latent heat of vaporization.

Usually $V_2 \ll V_1$, and this equation can be simplified to

dv/L

124 Problems in Solution on Thermodynamics and Statistical Mechanics

1128

(a) By equating the Gibbs free energy or chemical potential on the two sides of the liquid-vapor coexistence curve derive the Clausius-Clapeyron

, where q is the heat of vaporization per

particle and V_L is the volume per particle in the liquid and V_V is the

equation: --

volume per particle in the vapor.

$Q dP$

$dT T V_V - VL)$

(b) Assuming the vapor follows the ideal gas law and has a density

which is much less than that of the liquid, show that $p \propto \exp(-q/kT)$,

when the heat of vaporization is independent of T .

(wis co nsin)

Solution:

(a) From the first law of thermodynamics

$$dp = -SdT + Vdp$$

and the condition that the chemical potential of the liquid is equal to that of the vapor at equilibrium, we obtain

It follows that

$$\frac{dP}{dT} = \frac{S_V - S_L}{V_V - V_L}$$

With $q = T(S_V - S_L)$, we have

which is the Clausius-Clapeyron equation.

(b) If the vapor is regarded as an ideal gas, we have

Because the density of vapor is much smaller than that of liquid, we can neglect V_L in the Clausius-Clapeyron equation and write

The solution is $p \propto \exp(-q/kT)$.

Thermodynam'ca 126

1129

A gram of liquid and vapor with heat of vaporization L is carried around the very flat reversible cycle shown in Fig. 1.34. Beginning at point A , a volume V_1 of liquid in equilibrium with a negligible amount of its saturated vapor is raised in temperature by ΔT and in pressure by Δp so as to maintain the liquid state. Then heat is applied at constant pressure and the volume increases to V_2 leaving a negligible amount of liquid. Then the pressure is lowered by Δp and the temperature decreased by ΔT so that essentially all the material remains in the vapor state. Finally, heat is removed, condensing essentially all the vapor back into the liquid state at point A .

Consider such a Carnot cycle and write the change of boiling point with pressure, dT/dp , for the liquid in terms of the heat of vaporization and other quantities.

(wis co nsin)

I i II

V_1, V_2, V

Fig. 1.34.

Solution:

In this cycle, the process at constant pressure is isothermal. We assume the net heat absorbed by the system is Q . Then its efficiency is $\eta = Q/L$.

For the reversible Carnot cycle, the efficiency is $\eta = \Delta T/T$, giving $Q = L \Delta T/T$.

Q must be equal to the external work W of the system in the cycle, $W = \Delta p(V_2 - V_1)$, so that

$$\Delta p(V_2 - V_1) = L \frac{\Delta T}{T}$$

$dT/dp =$

$$\frac{L}{\Delta p(V_2 - V_1)}$$

T

Therefore,

$$AT - T(V_2 - V_1)$$

$$dT/dp = \lim_{\Delta p \rightarrow 0} \frac{\Delta T}{\Delta p} = \dots$$

$$\Delta p \rightarrow 0 \quad \Delta p \quad L^*$$

126 Problems & Solutions on Thermodynamics & Statistical Mechanics

1130

(a) Deduce from the 1st and 2nd laws of thermodynamics that, if a substance such as H_2O expands by $0.091 \text{ cm}^3/\text{g}$ when it freezes, its freezing temperature must decrease with increasing pressure.

(b) In an ice-skating rink, skating becomes unpleasant (i.e., falling frequently) if the temperature is too cold so that the ice becomes too hard.

Estimate the lowest temperature of the ice on a skating rink for which ice skating for a person of normal weight would be possible and enjoyable.

(The latent heat of ice is 80 cal/g).

Solution:

(SUNY, Buffalo)

Denote the liquid and solid phases by 1 and 2 respectively.

(a) The condition for coexistence of the two phases is

$$p_2 = p_1, \text{ so that } dp_2 = dp_1,$$

giving

$$V_2 dp_2 - S_2 dT_2 = V_1 dp_1 - S_1 dT_1.$$

As $p_2 = p_1 = p$ and $T_2 = T_1 = T$ on the coexistence line, we have

For regions whose temperatures are higher than those of phase transformation

we have $T > T_c$, and for the regions whose temperatures are

lower than those of phase transformation we have $T < T_c$. This means

that

i.e., for any temperature, $S_1 > S_2$.

$$\left(\frac{\partial S}{\partial T} \right)_p < 0 \text{ phase line}$$

For substances such as water, $V_2 > V_1$, so

(b) The lowest temperature permitted for enjoyable skating is the temperature at which the pressure on the coexistence line is equal to the

pressure exerted by the skater on ice. The triple point of water is at

$T_0 = 273.16 \text{ K}$, $p_0 = 1 \text{ atm}$. For a skater of normal weight $p \approx 10 \text{ atm}$,

so that

$$\frac{(P - P_0)}{T_{\text{min}} - T_0} = -\frac{h}{T_{\text{min}} \Delta V}.$$

Thermodynamic

With $h = 80 \text{ cal/g}$, $\Delta V = 0.091 \text{ cm}^3/\text{g}$, we have

127

$$T_0 = (1 - 2.5 \times 10^{-3}) T_0 = -0.06^\circ \text{C}.$$

$$\frac{(P - P_0) \Delta V}{T_{\text{min}} h} =$$

h

1131

The following data apply to the triple point of H_2O .

Temperature: 0.01°C ; Pressure: 4.6 mmHg

Specific volume of solid: $1.12 \text{ cm}^3/\text{g}$

Specific volume of liquid: $1.00 \text{ cm}^3/\text{g}$

Heat of melting: 80 cal/g

Heat of vaporization: 600 cal/g .

(a) Sketch a p - T diagram for H_2O which need not be to scale but which should be qualitatively correct. Label the various phases and critical points.

- (b) The pressure inside a container enclosing H₂O (which is maintained at T = -1.0°C) is slowly reduced from an initial value of 105 mmHg. Describe what happens and calculate the pressure at which the phase changes occur. Assume the vapor phase behaves like an ideal gas.
- (c) Calculate the change in specific latent heat with temperature dL/dT at a point (p, T) along a phase equilibrium line. Express your result in terms of L and the specific heat C_v, coefficient of expansion α, and specific volume V of each phase at the original temperature T and pressure p.
- (d) If the specific latent heat at 1 atm pressure on the vaporization curve is 540 cal/g, estimate the change in latent heat 10°C higher than the curve. Assume the vapor can be treated as an ideal gas with rotational degrees of freedom.

(MITI)

Solution:

(a) The p - T diagram of H₂O is shown in Fig. 1.35.

(b) The Clausius-Clapeyron equation gives

$$= -2.4 \text{ cal/cm}^3 \cdot -L K .$$

ice-water T(V_{water} - V_{ice})

$$\left(\frac{dL}{dT} \right) > 0 \text{ water-vapor}$$

When the pressure, which is slowly reduced, reaches the solid-liquid phase line, heat is released by the water while the pressure remains unchanged until all the water is changed into ice. Then at the vapor-solid line, the ice absorbs heat until it is completely changed into vapor. Afterwards the pressure begins to decrease while the vapor phase is maintained.

The pressure at which water is converted to ice is given by

T - T₀

$$\sim = 6.3 \times 10^3 \text{ cmHg}$$

L

$$p_{\text{water-ice}} = p_0 + \frac{L}{V_{\text{water}} - V_{\text{ice}}} \ln \frac{T}{T_0}$$

where we have used the values T = 272.15 K, T₀ = 273.16 K and p₀ =

4.6 mmHg. As V_{vapor} = - > Kce, we have

kT

Pm

$$-dP = - \frac{L}{TV_{\text{vapor}}} - m \frac{Lp}{T^2}$$

$$\frac{dT}{T^2} = \frac{L}{TV_{\text{vapor}}} + \frac{mLp}{T^3}$$

The pressure at which ice is converted to vapor is

$$p_{\text{ice-vapor}} = p_0 \exp \left[\frac{L}{R} \left(\frac{1}{T_0} - \frac{1}{T} \right) \right] = 4.4 \text{ mmHg}$$

where R is the molecular mass of water.

Thermodynamic a 129

(c) From $L = T(S_1 - S_2)$, we have

As $dS_1 = -CdPT_1 - a_1V_1dp$, where $a_1 = - \left(\frac{\partial S}{\partial T} \right)_{P, V_1}$, we have

$$\frac{dT}{T} = \frac{dV_1}{V_1} - \frac{dP}{P} - \frac{dV_2}{V_2}$$

we obtain

$$\frac{dL}{dT} = \frac{L}{T} - \frac{C_{p1} - C_{p2}}{T} - (a_1V_1 - a_2V_2) - \dots$$

(d) Let 1 and 2 stand for water and vapor respectively.

From $V_2 \gg V_1$, we know

where $a_2 = 1/T$, so $\Delta L = (C_{p1} - C_{p2})AT$.

2
9

Letting $C_{p1} = 1 \text{ cal/g}^\circ\text{C}$, $C_{p2} = -R \text{ cal/g}^\circ\text{C}$, $AT = 10^\circ\text{C}$, we get

$\Delta L = 6 \text{ cal/g}$.

1132

(a) Derive an expression for the dependence of the equilibrium vapor pressure of a material on the total pressure (i.e., how does the equilibrium partial pressure of a material depend on the addition of an overpressure of some inert gas?).

(b) Use this result to discuss qualitatively the difference between the triple point and the ice point of water.

(was *conclusion*)

130 Problem 8 8 Solution on Thermodynamics 8 Statistical Mechanics

Solution:

$x \ll 1$. Thus the mole chemical potential of the solution is

(a) We assume the mole concentration of the solute in the solution is

$$\mu_1(p, T) = \mu_1^0(p, T) - xRT,$$

where $\mu_1(p, T)$ is the mole chemical potential of the pure solvent. If the mole chemical potential of the vapor phase is $\mu_1^g(p, T)$, the equilibrium vapor pressure of the solvent, p_0 , is determined by

$$\mu_1^g(p_0, T_0) = \mu_1^l(p_0, T_0).$$

When the external pressure (the total pressure) is p , the condition of equilibrium of vapor and liquid is

Making use of Taylor's theorem, we have from the above two equations

Using the thermodynamic relation $dp = -SdT + Vdp$, we can write the above as

$$p - p_0 = [(S_2 - S_1)(T - T_0) - xRT]/(V_2 - V_1),$$

or

$$p_0 = p - [L(T - T_0)/T - xRT]/(V_2 - V_1),$$

where V is the mole volume, S is the mole entropy, and L is the latent heat, $L = T(S_2 - S_1)$.

(b) The triple point of water is the temperature T_0 at which ice, water and vapor are in equilibrium. The ice point is the temperature T at which pure ice and air-saturated water are in equilibrium at 1 atm. Utilizing the result in (a) we have

$$T - T_0 = T(V_2 - V_1)(p - p_0)/L + xRT_0^2/L,$$

where V_1 and V_2 are respectively the mole volumes of ice and water. From $V_2 > V_1$ and $L < 0$, we know the ice point is lower than the triple point.

Thermodynamics 131

The first term of the above formula comes from the change of pressure, the second term appears because water is not pure. The quantitative result of the first term is -0.0075 K, of the second term is -0.0023 K.

1133

Some researchers at the Modford Institute of Taxidermy claim to have measured the following pressure-temperature phase diagram of a new substance, which they call "embalmium". Their results show that along the phase lines near the triple point

$$\left(\frac{\partial T}{\partial p}\right)_{\text{sublimation}} < \left(\frac{\partial T}{\partial p}\right)_{\text{fusion}} < \left(\frac{\partial T}{\partial p}\right)_{\text{vaporization}}$$

as indicated in the diagram. If these results are correct, "embalmium" has one rather unusual property and one property which violates the laws of thermodynamics. What are the two properties?

(MIT)

PI

$$\left(\frac{\partial T}{\partial p}\right)_{\text{fusion}} < 0$$

Fig. 1.36.

Solution:

The property $\left(\frac{\partial T}{\partial p}\right)_{\text{fusion}} < 0$ is unusual as only a few substances like water behaves in this way. The Clausius-Clapeyron equation gives

$$\left(\frac{\partial T}{\partial p}\right)_{\text{vaporization}} = \frac{1}{\Delta S_{\text{vaporization}}} \Delta V_{\text{gas}}$$

$$\left(\frac{\partial T}{\partial p}\right)_{\text{sublimation}} = \frac{1}{\Delta S_{\text{sublimation}}} \Delta V_{\text{gas}}$$

$$\left(\frac{\partial T}{\partial p}\right)_{\text{sublimation}} < 0 \Rightarrow \Delta S_{\text{sublimation}} < 0$$

means $S_{\text{solid}} > S_{\text{liquid}}$, i.e., the mole

entropy of the solid phase is greater than that of the liquid phase, which violates the second law of thermodynamics, since a substance absorbs heat to transform from solid to liquid and the process should be entropy increasing.

132 Problems and Solutions on Thermodynamics and Statistical Mechanics

1134

The latent heat of vaporization of water is about $2.44 \times 10^4 \text{ J/kg}$ and the vapor density is 0.598 kg/m^3 at 100°C . Find the rate of change of the boiling temperature with altitude near sea level in $^\circ\text{C}$ per km. Assume the temperature of the air is 300 K .

(Density of air at 0°C and 1 atm is 1.29 kg/m^3).

(Use $\cos \theta \approx 1 - \frac{1}{2}\theta^2$)

Solution:

The Boltzmann distribution gives the pressure change with height: where $p(z)$ is the pressure at sea level $z = 0$, m is the molecular weight of air, and $T_0 = 300 \text{ K}$ is the temperature of the atmosphere. The Clausius-Clapeyron equation can be written as

$$\frac{dp}{p} = -\frac{L}{RT^2} dz$$

with $\rho_1 = 1000 \text{ kg/m}^3$, $\rho_2 = 0.598 \text{ kg/m}^3$ and $L/M = 2.44 \times 10^6 \text{ J/kg}$, we have

$$\rho_1 - \rho_2 = 1.40 \times 10^6 \text{ J/m}^3$$

($\rho_1 - \rho_2$)

So the rate of change of the boiling point with height is

Using the equation of state for ideal gas $p = \rho R T / M$, we have near the sea level

where $\rho = 1.29 \text{ kg/m}^3$ is the density of air, $g = 9.8 \text{ m/s}^2$ and $T(0) = 100^\circ\text{C}$.

dT

dz

Thus $\frac{dT}{dz} = -0.87^\circ\text{C/km}$.

Thermodynamics 133

1135

A long vertical cylindrical column of a substance is at temperature T in a gravitational field g . Below a certain point along the column the substance is found to be a solid; above that point it is a liquid. When the temperature is lowered by ΔT , the position of the solid-liquid interface is observed to move upwards a distance l . Neglecting the thermal expansion of the solid, find an expression for the density ρ_l of the liquid in terms of the density ρ_s of the solid, the latent heat L of the solid-liquid phase transition, g and the absolute temperature T and ΔT .

Assume that $\Delta T/T \ll 1$.

(Princeton)

Solution:

The Clausius-Clapeyron equation gives

$\frac{dL}{L} = \frac{dT}{T} - \frac{dp}{\rho_l g}$

In the problem, $dL = -\Delta T$, $dp = -\rho_l g l$. Hence

1136

- (a) Use simple thermodynamic considerations to obtain a relation between $\frac{dT}{dT_m}$, the logarithmic rate of variation of melting point with change of pressure, the densities of the solid and liquid phases of the substance in question and the latent heat of melting. (You may find it convenient to relate the latent heat to the entropy change.)
- (b) Use simple hydrostatic considerations to relate the pressure gradient within the earth to the earth's density and the acceleration of gravity. (Assume that the region in question is not at great depth below the surface.)
- (c) Combine the foregoing to calculate the rate of variation of the melting point of silicate rock with increasing depth below the earth's surface $\frac{dT_m}{dz}$.

$\frac{dT_m}{dz}$

134 Problems & Solutions on Thermodynamics & Statistical Mechanics

in a region where the average melting point of the rock is 1300°C . Assume a density ratio

$\frac{\rho_{\text{liquid}}}{\rho_{\text{solid}}} = 0.9$

and a latent heat of melting of 100 cal/g . Give your answer in degrees C per kilometer.

(UC, Berkeley)

Solution:

(a) During the phase transition, $\rho_l = \rho_s$, where l and s represent liquid phase and solid phase respectively. By thermodynamic relation

$$dp = -SdT + VdP,$$

we have $(S_l - S_s)dT = (V_l - V_s)dP$, so

$$\frac{dT}{dz} = \frac{V_l - V_s}{S_l - S_s} \frac{dP}{dz} = \frac{V_l - V_s}{S_l - S_s} \rho g,$$

$$\frac{dT_m}{dz} = \frac{V_l - V_s}{S_l - S_s} \rho g L$$

Substituting $V = l/\rho$ into the equation above, we get

$$\frac{dP}{dz}$$

$$dz$$

(b) Denote the depth as z , we have $\rho = \rho_0 + \rho_0 \alpha z$.

(c) From the above results, we have

$$= 37 \times 10^{-6} \text{C/cm} = 3.7 \text{C/km}.$$

1137

The vapor pressure, in mm of Hg, of solid ammonia is given by the relation: $\ln p = 23.03 - 3754/T$ where T = absolute temperature.

The vapor pressure, in mm of Hg, of liquid ammonia is given by the relation: $\ln p = 19.49 - 3063/T$.

(a) What is the temperature of the triple point?

(b) Compute the latent heat of vaporization (boiling) at the triple point. Express your answer in cal/mole. (You may approximate the behavior of the vapor by treating it as an ideal gas, and may use the fact that the density of the vapor is negligibly small compared to that of the liquid.)

(c) The latent heat of sublimation at the triple point is 7508 cal/mole.

(UC, Berkeley)

What is the latent heat of melting at the triple point?

Solution:

$\ln p = 19.49 - 3063/T$, which gives $T = 195 \text{ K}$.

(a) The temperature T of the triple point satisfies the equation 23.03

(b) From the relation between the vapor pressure and temperature of liquid ammonia

$$\ln p = C - 3063/T,$$

$$\text{we get } dp/dT = 3063p/T^2.$$

The Clausius-Clapeyron equation $-dp = -L/T^2$ then gives

$$dT = TV$$

$$L = 3063pV/T = 3063R = 2.54 \times 10^4 \text{ J/mol}$$

$$= 6037 \text{ cal/mol}.$$

(c) Denote S_v, S_l and S_s as the entropy for vapor, liquid and solid at triple point. Then the latent heat of vaporization is $T(S_v - S_l)$, that of sublimation is $T(S_v - S_s)$, and that of melting is

$$T(S_l - S_s) = T(S_v - S_s) - T(S_v - S_l)$$

$$= 7508 - 6037 = 1471 \text{ cal/mol}.$$

1158

The high temperature behavior of iron can be summarized as follows.

(a) Below 900°C and above 1400°C a-iron is the stable phase.

(b) Between these temperatures b-iron is stable.

(c) The specific heat of each phase may be taken as constant: $C_a =$

$$0.775 \text{ J/g} \cdot \text{K}; C_b = 0.690 \text{ J/g} \cdot \text{K}.$$

What is the latent heat at each transition?

(UC, Berkeley)

136 Problems and Solutions on Thermodynamics and Statistical Mechanics

Solution:

Referring to Fig. 1.37, we regard the whole process as isobaric.

$$dS$$

Choose the entropy at T_1 as zero for the a-phase. Since $T = C$,

$$dT$$

one has

$$S = C \ln T + \text{const.}; S_b = C \ln T_b, S_c = S_b + C \ln T_c$$

The changes in chemical potential are

Since $\Delta p' = \Delta p$, we have
 $= 1.60 \times \text{J/g.K}$
 Therefore

$$= (C_p - C_v)T \ln \left(\frac{p_2}{p_1} \right) - \frac{L}{T} \ln \left(\frac{p_2}{p_1} \right)$$

$$= 23.7 \text{ J/g}$$

1139

Liquid helium-4 has a normal boiling point of **4.2 K**. However, at a pressure of **1 mm** of mercury, it boils at **1.2 K**. Estimate the average latent heat of vaporization of helium in this temperature range.

(UC, Berkeley)

Solution:

state for ideal gas

According to the Clausius-Clapeyron equation and the equation of

L

$$pV_g = RT,$$

L

$$dT \frac{L}{T^2} = \frac{dp}{T} \left(\frac{V_g - V_l}{T} \right)$$

$$\frac{dL}{dT} = -L \frac{dp}{p} \frac{T}{V_g - V_l}$$

and assuming L to be constant, we get

$$L = R \ln \left(\frac{p_2}{p_1} \right) \left(\frac{T_2}{T_1} \right)^{\frac{L}{R}}$$

Therefore $L = 93 \text{ J/mol}$.

1140

(a) The pressure-volume diagram shows two neighbouring isotherms in the region of a liquid-gas phase transition. By considering a Carnot cycle

between temperatures T and $T + dT$ in the region shown shaded in the diagram, derive the Clausius-Clapeyron equation relating vapor pressure and temperature, $dp/dT = L/(TAV)$, where L is the latent heat of vaporization per mole and AV is the volume change between gas and liquid per mole.

(b) Liquid helium boils at temperature $T_0 = 4.2 \text{ K}$ when its vapor pressure is equal to $p_0 = 1 \text{ atm}$. We now pump on the vapor and reduce the pressure to a much smaller value p . Assuming that the latent heat L is approximately independent of temperature and that the helium vapor density is much smaller than that of the liquid, calculate the approximate temperature T , of the liquid in equilibrium with its vapor at pressure p . Express your answer in terms of L , T_0 , p_0 , p , and any other required constants.

(CUSPEA)

138 Problem 8 Solutions on Thermodynamics & Statistical Mechanics

Solution:

(a) From the $p - V$ diagram, we can see that the work done by the working material on the outside world is $dW = dpAV$ in this infinitesimal Carnot cycle. The heat absorbed in the process is $Q = L$. The formula for

the efficiency of a Carnot engine gives $\eta = 1 - \frac{T}{T'}$

$$\text{Thus } -dP = -L \frac{dT}{TAV}$$

When He3 melts the volume increases. The accompanying plot is a sketch of the He3 melting curve from 0.02 to 1.2 K. Make a sketch to show the change in entropy which accompanies melting in this temperature range.

(wis c o nsin)

Thermodynamics 139

Fig. 1.39.

Solution:

From the Clausius-Clapeyron equation, we have

$$dp/dT = \frac{AS}{AV - dP \cdot dT - AV' dT}$$

When He3 melts, the volume increases, i.e., $AV > 0$.

When $0.02 \text{ K} < T < 0.32 \text{ K}$, because $- < 0, AS < 0$.

When $0.32 \text{ K} < T < 1.2 \text{ K}$, because $- > 0, AS > 0$.

When $T = 0.32 \text{ K}$, $AS = 0$. The results are shown in Fig. 1.39(b).

1142

The phase transition between the aromatic (a) and fragrant (f) phases of the liquid mythological-mercaptan is second order in the Ehrenfest scheme, that is, AV and AS are zero at all points along the transition line $p, -f(T)$.

Use the fact that $AV = V_a(T,p) - V_f(T,p) = 0$, where V_a and V_f are the molar volumes in phase a and phase f respectively, to derive the slope of the transition line, $dp, -t(T)/dT$, in terms of changes in the thermal expansion coefficient, α , and the isothermal compressibility, κ_T at the transition.

(MIT)

Solution:

Along the transition line, one has

$$V_a(T, P) = V_f(T, P)$$

$$\text{Thus } dV_a(T, p) = dV_f(T, p).$$

1143

State Curie's law for the magnetization of a paramagnetic gas. Why does the magnetization depend on temperature? What modification of the law is necessary as $T \rightarrow 0$?

(wis c o nsin)

Solution:

Curie's law states that the magnetization of a paramagnetic substance in a magnetic field is inversely proportional to the absolute temperature:

$$M = CH/T, \text{ where } C \text{ is the Curie constant. As the temperature changes,}$$

so does the distribution of the directions of spins of the atoms and ions;

thus the magnetization is dependent on T .

At low temperatures the paramagnetic phase changes into the ferromagnetic phase. At this time, the external magnetic field B , produces a certain magnetization M , which in turn produces an exchange magnetic

field $B_E = \chi M$ (A is a constant). From $M = \chi(B + B_E) = \chi(B + \chi M)$

and $\chi = C/T$ (Curie's law), we have

$$M C X = -B, - T - T_c$$

where $T_C = C X$ is the Curie temperature.

Thermodynamics 141

1144

A substance is found to have two phases, N and S . In the normal state, the N phase, the magnetization M is negligible. At a fixed temperature $T < T_c$, as the external magnetic field H is lowered below the critical field

$$H_c(T) = H_0 \left[1 - \left(\frac{T}{T_c} \right)^2 \right],$$

the normal state undergoes a phase transition to a new state, the S phase.

In the S state, it is found that $B = 0$ inside the material. The phase diagram is shown below.

(a) Show that the difference in Gibbs free energies (in cgs units) between the two phases at temperature $T < T_c$ is given by

$$G_S(T, H) - G_N(T, H) = K[H - H_c(T)].$$

(You may express your answer in another system of units. The Gibbs free energy in a magnetic field is given by $G = U - TS - HM$.)

(b) At $H = H_c$, compute the latent heat of transition L from the N to the S phase. (Hint: one approach is to consider a "Clausius-Clapeyron" type of analysis.)

(c) At $H = 0$, compute the discontinuity in the specific heat as the material transforms from the N to the S phase.

(d) Is the phase transition first or second order at $H = 0$?

(UC, Berkeley)

$\frac{H}{A}$ nhnca

H_0 h G

(T : const $< T_c$)

Fig. 1.41. Fig. 1.42

Solution:

(a) Differentiating the expression for Gibbs free energy, we find $dG = -SdT - MdH$, where $B = H + 4\pi r M$ in cgs units. Referring to Fig. 1.42, we have

N phase: $M = 0$, $G_N = G_0(T)$,

142 Problems & Solutions on Thermodynamics & Statistical Mechanics

S phase: $B = 0$, $M = -H/4a$.

Integrating $dG = -MdH$, we obtain

$$G_S = H^2/87r + \text{const}$$

Noting that $G_S(H_c, T_c) = G_0(T_c)$ at the transition point, we have

1

871.

$$G_S = G_0(T) + \frac{1}{2} \mu_0 H^2 - H M$$

It follows that

$$G_S - G_N = -\frac{1}{2} \mu_0 H^2 - H M$$

(b) Since $S = - \left(\frac{\partial G}{\partial T} \right)_H$,

we have

$$= \frac{1}{2} \mu_0 H^2 + H M$$

$$- \frac{1}{2} \mu_0 H^2 - H M$$

2a T, "

When $H = 0$, $C_S - C_N = H/aT$,

(d) At $H = 0$, $L = 0$, $C_S - C_N \neq 0$, therefore the phase transition is second order.

1145

The phase boundary between the superconducting and normal phases of a metal in the H - T plane (H = magnitude of applied external field) is given by Fig. 1.43.

Thermodynamics 143

The relevant thermodynamic parameters are T, p , and H . Phase equilibrium requires the generalized Gibbs potential G (including magnetic parameters) to be equal on either side of the curve. Consider state A in the normal phase and A' in the superconducting phase; each lies on the phase boundary curve and has the same T, p and H but different entropies and magnetizations. Consider two other states B and B' arbitrarily close to A and A' ; as indicated by $p_A = p_B$.

(a) Use this information to derive a Clapeyron-Clausius relation (that is, a relation between the latent heat of transition and the slope dH/dT of the curve). What is the latent heat at either end of the curve? (For a long rod-shaped superconducting sample with volume V oriented parallel to the field, the induced magnetic moment is given by $M = -VH/4\pi r$; in the normal state, set $M = 0$.)

(b) What is the difference in specific heats at constant field and pressure (C_p, \sim, for) the two phases? What is the discontinuity in C_p, \sim, at $H=0, T=T_c, \text{? At } T=0, H=H_c, \text{?}$

(Prince ton)

Solution:

Fig. 1.43.

(a) $dG = -SdT + Vdp - MHdH,$

The condition of phase equilibrium is

Thus $dG = dG'$.

With $dp = 0$, one obtains for the superconducting sample

144 Problems on Thermodynamics & Statistical Mechanics

where $L = T(S - S')$ is the latent heat of phase transition. At the two ends of the curve: $H(T_c) = 0$ at $T = T_c$, gives $L = 0$; $dH/dT = 0$ at $T = 0$ gives $L = 0$ also.

(b) From the above equation, we have

$$S' - S = -VH, \quad -dH,$$

$$41r \quad dT.$$

$$\text{As } C = T(dS/dT)$$

At $T = T_c$, $H = 0$, we have

At $T = 0$, $H = H_c$, we have

$$AC = -VHT, \quad [F] d^2H = 0$$

$$47r \quad T=0$$

1146

A simple theory of the thermodynamics of a ferromagnet uses the free energy F written as a function of the magnetization M in the following

form: $F = -HM + FO + A(T - T_c)M^2 + BM^4$, where H is the magnetic field, F_0 , A , B are positive constants, T is the temperature and T_c is the critical temperature.

- What condition on the free energy F determines the thermodynamic equilibrium value of M for $T > T_c$, and sketch a graph of M versus T for small constant H .
- Determine the equilibrium value of M for $T > T_c$, and sketch a graph of M versus T for small constant H .
- Comment on the physical significance of the temperature dependence of M as T gets close to T_c , for small H in case (b).

(Wisconsin)

Thermodynamics 145

Solution:

According to the problem F denotes the Gibbs function.

(a) $F = \text{minimum}$ is the condition to determine the most probable value of M in equilibrium. Thus M is determined from $(\partial F / \partial M)_{T,H} = 0$.

$$(b) (\partial F / \partial M)_{T,H} = -H + 2A(T - T_c)M + 4BM^3 = 0. (*)$$

If $2A(T - T_c)M \gg 4BM^3$, that is, if T is far from T_c , we have

$$M = \frac{H}{2A(T - T_c)}$$

This is the Curie-Weiss law. The change of M with T is shown in Fig. 1.44.

(c) If $H = 0$, the equation (*) has solutions

$$M = 0, \quad M = \pm \sqrt{A(T - T_c) / 2B}$$

For stability consider

$$\left(\frac{\partial^2 F}{\partial M^2} \right)_{T,H} = 2A(T - T_c) + 12BM^2$$

When $T > T_c$, the only real solution, $M = 0$, is stable;

Fig. 1.44

when $T < T_c$, the $M = 0$ solution is unstable, while the solution $M = \pm \sqrt{A(T - T_c) / 2B}$ is stable. When $T = T_c$, $M = 0$, is the point of phase transition of the second order. (If $T > T_c$, the substance is paramagnetic; if $T < T_c$, the substance is ferromagnetic.)

If $H \neq 0$, (*) requires $M \neq 0$. Then as long as $M^2 > A(T_c - T) / 6B$, the system is stable. When $T = T_c$, $2A(T - T_c)M \ll 4BM^3$, and (*) has the solution $M = (H/4B)^{1/3}$. Thus T_c is the point of first-order phase transition.

$$M = \sqrt[3]{A(T - T_c) / 4B}$$

146 Problems and Solutions in Thermodynamics ©4 Statistical Mechanics

1147

In the absence of external magnetic fields a certain substance is superconducting for temperatures $T < T_0$. In the presence of a uniform field B

and for $T < T_d$, the system can exist in two thermodynamic phases:

For $B < B_c(T)$, it is in the superconducting phase and in this phase the magnetization per unit volume is

(Superconducting phase) $M = -B/4s$.

For $B > B_c(T)$, the system is in the normal phase and here (Normal phase) $M = 0$.

The two phases can coexist in equilibrium along the curve $B = B_c(T)$ in the $B - T$ plane.

Evidently there is a discontinuity in magnetization across the coexistence curve. There is also a discontinuity in entropy. Let $S_N(T)$ and

$S_S(T)$ be the entropies per unit volume respectively for the normal and superconducting phases along the coexistence curve. Given that $B_c(T) =$

$B_0(1 - T/T_0)$, compute $\Delta S = S_N(T) - S_S(T)$ as a function of T and the other parameters.

(CUSPEA)

(3

Solution:

Comparing this magnetic system with a p - V system, we have $-B \rightarrow P$ and $M \rightarrow V$. From the Clausius-Clapeyron equation of the $p - V$ system,

$dp/dT = \Delta S / \Delta V$

we have for the magnetic system, on the line of two-phase coexistence,

$-dB/dT = \Delta S / \Delta M$

where $\Delta S = S_N - S_S$, $\Delta M = M_N - M_S = B/4s$.

Therefore

$\Delta S = -4s \Delta M dB/dT$

where $\Delta S = S_N - S_S$, $\Delta M = M_N - M_S = B/4s$.

Therefore

$\Delta S = -4s \Delta M dB/dT$

at 2

(Note: An assumption has been made here that the pressing of the fluid created by the disturbances is adiabatic for which $S = \text{const}$. Generally speaking, such approximation is reasonable as the heat conductivity is negligible.)

(b) At $T = 0$ K, for a system of spin $1/2$ Fermion gas we have

$2 N P_0$

$P = \frac{2}{3} n \epsilon$

1150

Gas, in equilibrium at pressure p_0 and mass density ρ_0 , is confined to a cylinder of length L and cross sectional area A . The right hand end of the cylinder is closed and fixed. At the left hand end there is a frictionless and massless movable piston. In equilibrium the external force that must be exerted on the piston is of course $F_0 = p_0 A$. However, suppose

a small additional force is supplied by an external agency: the harmonic force $f(t) = f_0 \cos(\omega t)$. This produces small motions of the piston and thus small amplitude disturbances in the gas. Let c be the speed of sound in the gas; neglect viscosity. Let $v(t)$ be the velocity of the piston. Compute $\mathbf{v}(\mathbf{r}, t)$. (CUSPEA)

piston
/

., * x

-L Fig.

1.4F.

Solution:

whose origin is the equilibrium point (as shown in Fig. 1.46).

Consider the gas as an ideal fluid. We choose a coordinate system

Let the

150 Problems in Solution on Thermodynamics and Statistical Mechanics

velocity of the macroscopic motion of the gas be $\mathbf{u}(\mathbf{x}, t)$ and the pressure of the gas be $p(\mathbf{x}, t)$. Because the displacement of the piston is very small, we can solve $\mathbf{u}(\mathbf{z}, t)$ and $p(\mathbf{z}, t)$ approximately in the region $0 \leq z \leq L$ and consider $\mathbf{u}(\mathbf{0}, t)$. The boundary conditions are $p(0, t) = f(t)/A$ and $\mathbf{u}(L, t) = \mathbf{0}$. As $f(t)$ is a sinusoidal function of t and the frequency is ω , the resulting $\mathbf{u}(\mathbf{z}, t)$ and $p(\mathbf{z}, t)$ must be waves of frequency ω and wave vector $\mathbf{k} = \omega/c$. In fact, $\mathbf{u}(\mathbf{z}, t)$ and $p(\mathbf{z}, t)$ both satisfy the wave equation with propagating velocity c . We can write

$$f(\mathbf{r}) = \text{Re} \{ \exp(i\omega t) \},$$

$$p = \text{Re} \{ \phi(\mathbf{z}) \exp(i\omega t) \},$$

$$\mathbf{u} = \text{Re} \{ \mathbf{u}(\mathbf{z}) \exp(i\omega t) \}.$$

Thus, to satisfy the boundary condition of p , we have

$$\phi(z) = -f_0 \cos(kz) + X \sin(kz), \quad A$$

where X is to be determined.

equation

On the other hand, the macroscopic motion of fluid satisfies the Euler

au ap

$$\rho_0 \frac{\partial \mathbf{u}}{\partial t} = -\nabla p$$

where ρ_0 is the average density, \mathbf{u} is the velocity and p is the pressure. Then

$$\mathbf{G}(\mathbf{x}) = -i(k-p \sin kx + X \cos kz), \quad \text{where } \rho_0 = -\frac{f_0}{c}$$

$\rho_0 A$

Using the boundary condition $\mathbf{u}(L) = 0$, we have

$$X = \rho_0 \tan(kL).$$

Thus

$$i\mathbf{k} \cdot \rho_0 \mathbf{u} = \rho_0 \omega \mathbf{u}$$

$$\mathbf{c}(\mathbf{x} = 0) = -\rho_0 \tan kL = -\tan kL. \quad \text{WP3 } c \rho_0 c$$

$$\sim (t) \text{Re} \{ \exp(i\omega t) \} = -\tan kL \exp(i\omega t)$$

1151

Under normal conditions the temperature of the atmosphere decreases steadily with altitude to a height of about 12 km (tropopause), above which the temperature rises steadily (stratosphere) to about 50 km.

(a) What causes the temperature rise in the stratosphere?

(b) The warm stratosphere completely surrounds the earth, above the cooler tropopause, maintained as a permanent state. Explain.

(c) Sound waves emitted by a plane in the tropopause region will travel

to great distances at these altitudes, with intensity decreasing, approximately, only as $1/R$. Explain

(Columbia)

Solution:

(a) The concentration of ozone in the stratosphere formed by the action of the sun's ultraviolet radiation on the oxygen of the air increases with altitude. The ozone absorbs the sun's ultraviolet radiation and raises the temperature of surrounding air.

(b) In the stratosphere, the ozone absorbs the ultraviolet radiation of the sun while the carbon dioxide CO_2 there radiates infrared radiation, resulting in an equilibrium of energy.

(c) Sound waves tend to deflect towards the region of lower velocity of propagation, i.e., of lower temperature. In the tropopause, temperature increases for both higher and lower altitudes. Hence the sound waves there are confined to the top layer of the troposphere, spreading only laterally in

fan-shape propagation so that the intensity decreases approximately as $1/R^2$ instead of $1/R$.

R2

1152

Since variations of day and night in temperature are significantly damped at a depth of around 10 cm in granite, the thermal conductivity of granite is 5×10^{-1} cal/s.cm°C.

(Columbia)

Solution:

Assume that the temperature at the depth of 10 cm below the surface of granite is constant at $20^\circ C$. When the temperature is the highest in a day, the temperature of the ground surface is assumed to be $T_1 = T_0 + 10^\circ C$. The intensity of the solar radiation on the ground is

$$Q = 1400 \text{ W/m}^2 = 3.3 \times 10^8 \text{ cal/s.cm}^2$$

Q is completely absorbed by the earth within the first 10 cm below surface.

Then from the Fourier law of heat conduction, we obtain an estimate of the thermal conductivity of granite:

$$K = \frac{Q \cdot x}{A \cdot (T_1 - T_0)}$$

$$K = \frac{Q \cdot x}{A \cdot (T_1 - T_0)}$$

$$K = \frac{3.3 \times 10^8 \cdot 10}{1 \cdot 10} = 3.3 \times 10^7 \text{ cal/s.cm}^2 \cdot ^\circ C$$

$$= 3.3 \times 10^7 \text{ cal/s.cm}^2 \cdot ^\circ C$$

If we take into account reflection of the radiation from the earth's surface, the value of K will be smaller than the above estimate. Therefore we must choose the answer $5 \times 10^7 \text{ cal/s.cm}^2 \cdot ^\circ C$.

1153

The heat transferred to and from a vertical surface, such as a window pane, by convection in the surrounding air has been found to be equal to $0.41 \sim 0.45 (At)^{5/4} \text{ cal/sec.cm}^2$, where At is the temperature difference between the surface and the air. If the air temperature is $25^\circ C$ on the inside of a room and $-15^\circ C$ on the outside, what is the temperature of the inner surface of a window pane in the room? The window pane has a thickness of 2 mm and a thermal conductivity of $2 \times 10^{-2} \text{ cal/sec.cm}^2 \cdot ^\circ C$. Heat transfer by radiation can be neglected.

(Wisconsin)

Solution:

inner and outer surfaces to be respectively $t_1^\circ C$ and $t_2^\circ C$. Thus we have
We consider an area of 1 cm^2 , and assume the temperatures of the

A sheet of ice 1 cm thick has frozen over a pond. The upper surface of the ice is at -20°C .

- (a) At what rate is the thickness of the sheet of ice increasing?
(b) How long will it take for the sheet's thickness to double?

The thermal conductivity of ice κ is 5×10^{-2} cal/cm. sec.OC.

The latent heat of ice L is 80 cal/g. The mass density of water ρ is 1 g/cm³ cal/cm. sec.OC. The latent

(SUNY, Buffalo)

Solution:

- (a) Let the rate at which the thickness of the sheet of ice increases be

$\frac{dz}{dt}$ a point on the surface of ice be the origin of z -axis, and the thickness of ice be z .

The heat current density propagating through the ice sheet is $j = -\kappa \frac{dT}{dz}$ and the heat released by water per unit time per unit area

$\rho L \frac{dz}{dt}$

154 Problems in Thermodynamics & Statistical Mechanics

$\frac{dz}{dt} = \frac{\kappa (T - T_0)}{\rho L z}$

$dz dt$

is $\rho L \frac{dz}{dt}$. Hence we obtain the equation $\rho L \frac{dz}{dt} = -j$, giving $\frac{dz}{dt} = -\frac{j}{\rho L}$

$$-\frac{j}{\rho L} = \frac{\kappa (T - T_0)}{\rho L z}$$

- (b) The above expression can be written as

$$dt = \frac{\rho L z dz}{\kappa (T - T_0)}$$

$n(T - T_0)$

$$t = \frac{\rho L}{2\kappa n} \ln \left(\frac{z_2}{z_1} \right)$$

If we take $z_1 = 1$ cm and $z_2 = 2$ cm, then $At = 1.2 \times 10^3 \text{ s} = 20$ min.

1156

Consider a spherical black asteroid (made of rock) which has been ejected from the solar system, so that the radiation from the sun no longer

has a significant effect on the temperature of the asteroid. Radioactive elements produce heat uniformly inside the asteroid at a rate of $q = 3 \times 10^{-7}$ cal/g.sec. The density of the rock is $\rho = 3.5$ g/cm³, and the thermal conductivity is $k = 5 \times 10^{-4}$ cal/deg.cmsec. The radius of the asteroid is $R = 100$ km. Determine the central temperature T_c and the surface temperature T_s of the asteroid assuming that a steady state has been achieved.

(UC, Berkeley)

cal/deg.cmsec.

Solution:

The surface temperature satisfies

$4\pi R^2 q = Q$

$$4\pi R^2 q = Q = -3 \pi R^2 k \frac{dT}{dr} \Big|_{r=R}$$

so

$$T_c - T_s = \frac{3qR}{4k} = 22.5 \text{ K}.$$

The equation of heat conduction inside the asteroid is

$$\nabla \cdot (-k \nabla T) = Q$$

Using spherical coordinates, we have

Thermodynamics 155

and so

The central temperature is

$$T_c - T_s = \frac{3qR}{4k} = 22.5 \text{ K}.$$

- 6k

1157

Let H be the flow of heat per unit time per unit area normal to the isothermal surface through a point P of the body. Assume the experimental fact

$$H = -k \nabla T,$$

where T is the temperature and k is the coefficient of thermal conductivity.

Finally the thermal energy absorbed per unit volume is given by cpT , where c is the specific heat and ρ is the density.

(a) Make an analogy between the thermal quantities H, k, T, c, ρ and

(b) Using the results of (a) find the heat conduction equation.

(c) A pipe of inner radius r_1 , outer radius r_2 and constant thermal conductivity k is maintained at an inner temperature T_1 and outer temperature T_2 . For a length of pipe L find the rate the heat is lost and the temperature between r_1 and r_2 (steady state).

the corresponding quantities E, J, V, ρ of steady currents.

(SVNY, Bufiulo)

Solution:

(a) By comparison with Ohm's law $\mathbf{J} = \sigma \mathbf{E} = -\sigma \text{grad } V$ (V is voltage)

and conservation law of charge $\text{div } \mathbf{J} = -\frac{d\rho}{dt}$, we obtain the analogy

$$cpT \leftrightarrow \rho; H \leftrightarrow \mathbf{J}; \text{grad } T \leftrightarrow \text{grad } V; k \leftrightarrow \sigma.$$

(b) By the above analogy and charge conservation law, we have

$$cp \frac{dT}{dt} = -\text{grad} \cdot (-k \text{grad } T) = k \nabla^2 T.$$

at

Then the heat conduction equation is

$$\nabla^2 T = 0.$$

$$\nabla^2 T = 0.$$

(c) When equilibrium is reached, $\frac{dT}{dt} = 0$; hence $\nabla^2 T = 0$.

The boundary conditions are $T(r_1) = T_1$ and $T(r_2) = T_2$.
 Choosing the cylindrical coordinate system and solving the Laplace equation, we obtain the temperature between r_1 and r_2 :

$$T(r) = \frac{r_2^2 - r^2}{r_2^2 - r_1^2} T_1 + \frac{r^2 - r_1^2}{r_2^2 - r_1^2} T_2$$

we obtain the rate at which the heat is lost:

$$q = 2\pi r L h = 2\pi r k (T_1 - T_2) L / \ln \frac{r_2}{r_1}$$

1158

A uniform non-metallic annular cylinder of inner radius r_1 , outer radius r_2 , length l is maintained with its inner surface at 100°C and its outer surface at 0°C .

- (a) What is the temperature distribution inside?
 (b) If it is then placed in a thermally insulated chamber of negligible heat capacity and allowed to come to temperature equilibrium, will its entropy increase, decrease or remain the same? Justify your answer.

(Wisconsin)

Fig. 1.47.

ThemedyMmice 157

Solution:

(a) Because the material is uniform, we can assume the heat conductivity is uniform too. According to the formulas $dQ = -k(dT/dr)sd\tau$ and $s = 2\pi r l$, we have

$$dQ/dt = -2\pi r l k dT/dr$$

Since dQ/dt is independent of r , we require $dT/dr = A/r$, where A is a constant. Then $T(r) = A \ln r + B$.

From the boundary conditions, we have

$$T_2 - T_1 = A \ln \frac{r_2}{r_1}$$

$$A = \frac{T_2 - T_1}{\ln \frac{r_2}{r_1}}$$

$$B = T_1 - A \ln r_1$$

$$T(r) = \frac{T_2 - T_1}{\ln \frac{r_2}{r_1}} \ln \frac{r}{r_1} + T_1$$

where $T_1 = 373 \text{ K}$ and $T_2 = 273 \text{ K}$, so that

$$T(r) = \ln \frac{r}{r_1} \left[\frac{T_2 - T_1}{\ln \frac{r_2}{r_1}} \right] + T_1$$

$$T(r) = \ln \frac{r}{r_1} \left[\frac{(T_2 - T_1) \ln \frac{r}{r_1} + T_2 \ln \frac{r_1}{r_2} - T_1 \ln \frac{r_1}{r_2}}{\ln \frac{r_2}{r_1}} \right]$$

(b) This is an irreversible adiabatic process, so that the entropy increase ΔS .

1159

When there is heat flow in a heat conducting material, there is an increase in entropy. Find the local rate of entropy generation per unit volume in a heat conductor of given heat conductivity and given temperature gradient.

(UC, Berkeley)

Solution:

then $du = TdS$. The heat conduction equation is

If we neglect volume expansion inside the heat conducting material,

$$\text{div } \mathbf{q} = 0$$

Hence

$$dS/dt = -\text{div } \mathbf{q}/T = -\text{div } (\mathbf{q}/T) + \mathbf{q} \cdot \nabla (1/T)$$

where q/T is the entropy flow, and $\oint \mathbf{i}$ is the irreversible entropy increase due to the inhomogeneous temperature distribution. Thus, the local rate of entropy generation per unit volume is

158 Problems on Thermodynamics and Statistical Mechanics

According to Fourier's heat conduction law, $\mathbf{q} = -k\nabla T$, the above gives

$$S = k(\nabla T)^2$$

PART II

STATISTICAL PHYSICS

1. PROBABILITY AND STATISTICAL ENTROPY (2001-2013)

2001

A classical harmonic oscillator of mass m and spring constant k is known to have a total energy of E , but its starting time is completely unknown. Find the probability density function, $p(\mathbf{x})$, where $p(z)dz$ is the probability that the mass would be found in the interval dx at x .

(MIT)

Solution:

From energy conservation, we have

where A is the oscillating amplitude. So the period is

Therefore we have

$$p(z)dz = \dots$$

2002

Suppose there are two kinds of *E. coli* (bacteria), "red" ones and "green" ones. Each reproduces faithfully (no sex) by splitting into half, red+red or green+green, with a reproduction time of 1 hour. Other than the markers "red" and "green", there are no differences between them. A colony of 5,000 "red" and 5,000 "green" *E. coli* is allowed to eat and reproduce. In order to keep the colony size down, a predator is introduced which keeps the colony size at 10,000 by eating (at random) bacteria.

(a) After a very long time, what is the probability distribution of the number of red bacteria?

161

162 Problems on Thermodynamics and Statistical Mechanics

(b) About how long must one wait for this answer to be true?

(c) What would be the effect of a 1% preference of the predator for eating red bacteria on (a) and (b)?

(Princeton)

Solution:

(a) After a sufficiently long time, the bacteria will amount to a huge number $N \gg 10,000$ without the existence of a predator. That the predator eats bacteria at random is mathematically equivalent to selecting $n = 10,000$ bacteria out of N bacteria as survivors. $N \gg n$ means that in every selection the probabilities of surviving "red" and "green" *E. coli* are the same. There are 2^n ways of selection, and there are $\binom{N}{n}$ ways to survive n "red" ones. Therefore the probability distribution of the number of "red" *E. coli* is

1 1 #

$$-C^m = \dots, m=0,1, \dots, n$$

$$2^n 2^n m!(n-m)!$$

- (b) We require $N \gg n$. In practice it suffices to have $N/n = \ln 2$. As $N = 2^n$, $t = 6$ to 7 hours would be sufficient.
- (c) If the probability of eating red bacteria is

eating green is $\binom{n}{m} p^m (1-p)^{n-m}$, the result in (a) becomes

$$C^m = \binom{n}{m} p^m (1-p)^{n-m}$$

$$2^n n! m!(n-m)!$$

$$m!(n-m)!$$

The result in (b) is unchanged.

200s

- (a) What are the reduced density matrices in position and momentum spaces?
- (b) Let us denote the reduced density matrix in momentum space by $\rho(p)$.

Show that if $\rho(p)$ is diagonal, that is,

$$\rho(p) = \sum_i |p_i\rangle \langle p_i| \rho_i$$

then the diagonal elements of the position density matrix are constant.

(SUNY, Buffalo)

Solution:

- (a) The reduced density matrices are matrix expressions of density operator $\rho(t)$ in an orthogonal complete set of singlet states, where the density operator $\rho(t)$ is defined such that the expectation value of an arbitrary operator \hat{O} is $\langle \hat{O} \rangle = \text{tr}[\hat{O}\rho(t)]$. We know that an orthogonal complete set of singlet states in position space is $\{|r\rangle\}$, from which we can obtain the reduced density matrix in position space $\rho(r)$. Similarly, the reduced density matrix in momentum space is $\rho(p)$, where $\{|p\rangle\}$ is an orthogonal complete set of singlet states in momentum space.

$$\rho(r) = \sum_i |r_i\rangle \langle r_i| \rho_i$$

$$\rho(p) = \sum_i |p_i\rangle \langle p_i| \rho_i$$

$$\rho(r) = \sum_i |r_i\rangle \langle r_i| \rho_i$$

$$\rho(p) = \sum_i |p_i\rangle \langle p_i| \rho_i$$

Then the diagonal elements $\rho(r) = \sum_i \rho_i$ are obviously constant.

2004

- (a) Consider a large number of N localized particles in an external magnetic field \mathbf{H} . Each particle has spin $1/2$. Find the number of states accessible to the system as a function of M_z , the z-component of the total spin of the system. Determine the value of M_z for which the number of states is maximum.

- (b) Define the absolute zero of the thermodynamic temperature. Explain the meaning of negative absolute temperature, and give a concrete example to show how the negative absolute temperature can be reached.

(SUNY, Buffalo)

Solution:

- (a) The spin of a particle has two possible orientations $1/2$ and $-1/2$.

Let the number of particles with spin $1/2$ whose direction is along \mathbf{H} be

N_1 and the number of particles with spin $-1/2$ whose direction is opposite

to \mathbf{H} be N_2 ; then the component of the total spin in the direction of \mathbf{H} is

$$M_z = (N_1 - N_2) \frac{1}{2}$$

By $N_1 + N_2 = N$, we can obtain $N_1 = N + 2M_z$, and

$N_2 = N - 2M_z$. The number of states of the system is

$$\Omega = \binom{N}{N_1}$$

22

N

2

Using Stirling's formula, one obtains

$N!$

$$Nt \ln N! \ln Q = \ln \dots$$

BY $a \ln Q$

$$- \ln Nt + \ln(N - Nt) = 0, \quad a Nt$$

N

2

we get $NT = \dots$, i.e., $M = 0$ when the number of states of the system is maximum.

(b) See Question 2009.

2005

There is an one-dimensional lattice with lattice constant a as shown in Fig. 2.1. An atom transits from a site to a nearest-neighbor site every τ seconds. The probabilities of transiting to the right and left are p and $q = 1 - p$ respectively.

Fig. 2.1.

Statistical Physics 165

(a) Calculate the average position Z of the atom at the time $t = NT$,

(b) Calculate the mean-square value $(z - \langle z \rangle)^2$ at the time t .

where $N \gg 1$;

(MIT)

Solution:

the z -axis directing to the right. We have

(a) Choose the initial position of the atom as the origin $z = 0$, with

$$(2n - N)apnqN - n$$

$$N N!$$

-

$$= \int_0^1 n!(N - n)!$$

$$= 2aPG \left(\sum_{n=0}^N n!(N - n)! p^n q^{N-n} \right) - Na$$

$n=0$

$a N$

$$n=0 a$$

$a P$

$$= 2ap - (p + q)N - Na = Na(p - q).$$

2006

(a) Give the definition of entropy in statistical physics.

(b) Give a general argument to explain why and under what circumstances the entropy of an isolated system A will remain constant, or increase.

For convenience you may assume that A can be divided into subsystems

B and C which are in weak contact with each other, but which

themselves remain in internal thermodynamic equilibrium.

(UC, Berkeley)

Solution:

(a) $S = k \ln \Omega$, where k is Boltzmann's constant and Ω is the total number of microscopic states of the given macroscopic state.

(b) Assume that the temperatures of the two subsystems are T_B and

T_C respectively, and that $T_B \neq T_C$. According to the definition of entropy,

166 Problem 3 Solution on Thermodynamics & Statistical Mechanics

if there is a small energy exchange $A > 0$ between them (from B to C), then

When $T_B > T_C$, there is no thermal equilibrium between the subsystems, and $\Delta S > 0$;

When $T_B = T_C$, i.e., the two subsystems are in equilibrium, $\Delta S = 0$.

2007

Give Boltzmann's statistical definition of entropy and present its physical meaning briefly but clearly. A two-level system of $N = n_1 + n_2$ particles is distributed among two eigenstates 1 and 2 with eigenenergies E_1 and E_2 respectively. The system is in contact with a heat reservoir at temperature T . If a single quantum emission into the reservoir occurs, population changes $n_2 \rightarrow n_2 - 1$ and $n_1 \rightarrow n_1 + 1$ take place in the system. For $n_1 \gg 1$ and $n_2 \gg 1$, obtain the expression for the entropy change of

- (a) the two level system, and of
- (b) the reservoir, and finally
- (c) from (a) and (b) derive the Boltzmann relation for the ratio n_1/n_2 .

(UC, Berkeley)

Solution:

Physically entropy is a measurement of the disorder of a system.

$S = k \ln R$, where R is the number of microscopic states of the system.

(a) The entropy change of the two-level system is

ΔS

$$\Delta S = k \ln \frac{N!}{n_1! n_2!} - k \ln \frac{(n_1 + 1)! (n_2 - 1)!}{N!}$$

$$= k \ln \frac{N!}{n_1! n_2!} - k \ln \frac{(n_1 + 1)! (n_2 - 1)!}{N!}$$

$$= k \ln \frac{n_1! n_2!}{(n_1 + 1)! (n_2 - 1)!}$$

$$= k \ln \frac{n_2}{n_1 + 1}$$

(b) The entropy change of the reservoir is

Statistical Physica 167

(c) From $\Delta S + \Delta S_r = 0$, we have

$$-n_2 = \exp \left(- \frac{E_2 - E_1}{kT} \right)$$

n_1

2008

Consider a system composed of a very large number N of distinguishable atoms, non-moving and mutually non-interacting, each of which has only two (non-degenerate) energy levels: $0, \epsilon > 0$. Let E/N be the mean energy per atom in the limit $N \rightarrow \infty$.

(a) What is the maximum possible value of E/N if the system is not necessarily in thermodynamic equilibrium? What is the maximum attainable value of E/N if the system is in equilibrium (at positive temperature, of course)?

(b) For thermodynamic equilibrium, compute the entropy per atom,

(Princeton)

S/N , as a function of E/N .

Solution:

(a) If the system is not necessarily in thermodynamic equilibrium, the maximum possible value of E/N is ϵ ; and if the system is in equilibrium (at positive temperature), the maximum possible value of E/N is $\epsilon/2$ corresponding to $T \rightarrow \infty$.

(b) When the mean energy per atom is $E/N = \epsilon/2$, ϵ/s particles are on the

level of energy ϵ and the microscopic state number is

$$N! Q = \binom{N}{f} (N-f)! \cdot$$

So the entropy of the system is

$$S = k \ln \frac{N!}{f!(N-f)!}$$

$$S = k \ln \frac{N!}{f!(N-f)!}$$

168 Problems & Solutions on Thermodynamics & Statistical Mechanics

If $E/k \gg 1, N - E/k \gg 1$, we have

$$N!$$

r 1

$$= k \ln \frac{N!}{f!(N-f)!} \approx -k \ln \left(\frac{1}{f} \right)^f \left(\frac{1}{N-f} \right)^{N-f}$$

$$1 - EN$$

2009

Consider a system of N non-interacting particles, each fixed in position and carrying a magnetic moment μ , which is immersed in a magnetic field H . Each particle may then exist in one of the two energy states $E = 0$ or $E = 2\mu H$. Treat the particles as distinguishable.

(a) The entropy, S , of the system can be written in the form $S =$

$k \ln R(E)$, where k is the Boltzmann constant and E is the total system energy. Explain the meaning of $R(E)$.

(b) Write a formula for $S(n)$, where n is the number of particles in the upper state. Crudely sketch $S(n)$.

(c) Derive Stirling's approximation for large n :

$$\ln n! \approx n \ln n - n$$

by approximating $\ln n!$ by an integral.

(d) Rewrite the result of (b) using the result of (c). Find the value of

(e) Treating E as continuous, show that this system can have negative

(f) Why is negative temperature possible here but not for a gas in a (CUSPEA)

(a) $R(E)$ is the number of all the possible microscopic states of the n for which $S(n)$ is maximum.

absolute temperature.

box?

Solution:

system when its energy is E , where

Statistical Physics 169

(b) As the particles are distinguishable,

$$N!$$

$$= n!(N-n)! \cdot$$

$$N!$$

$$n!(N-n)!$$

Hence $S = k \ln$

We note that $S(n=0) = S(n=N) = 0$, and we expect $S_{,,}$ to appear

$$= S(n) \cdot$$

at $n = N/2$ (to be proved in (d) below). The graph of $S(n)$ is shown in Fig. 2.2.

n

$$(c) \ln n! = \sum_{m=1}^n \ln m \approx \int_1^n \ln x dx = n \ln n - n + 1 \approx n \ln n - n, \text{ (for } m=1)$$

large n).

$S = N \ln 2$

(d) $k_B \ln \Omega = k_B \ln \binom{N}{n} = k_B \ln \frac{N!}{n!(N-n)!}$

$\ln \frac{N!}{n!(N-n)!} = \ln N! - \ln n! - \ln (N-n)!$

$dS =$

$= 0$ gives

$\frac{dn}{n} =$

$\frac{d(N-n)}{N-n}$

$-\frac{1}{n} = -\frac{1}{N-n} \implies \ln(N-n) = \ln n + \text{const}$

$N-n = N \implies n = N/2$

Therefore, $S = S_{max}$, when $n = N/2$.

2.2

Fig. 2.2.

(e) As $E = nc$, $S = S_{max}$, when $E = -NE$. When $E > -NE$, $T < 0$

$\frac{1}{T} = \frac{dS}{dE}$

$\frac{1}{T} =$

$\frac{dS}{dE}$

(see Fig. 2.2). Because $T < 0$ we have $\frac{dS}{dE} < 0$ when $E > -NE$.

(f) The reason is that here the energy level of a single particle has an upper limit. For a gas system, the energy level of a single particle does not have an upper limit, and the entropy is an increasing function of E ; hence negative temperature cannot occur.

From the point of view of energy, we can say that a system with negative temperature is "hotter" than any system with a positive temperature.

170 *Problems in Thermodynamics & Statistical Mechanics*

2010

A solid contains N magnetic atoms having spin $1/2$. At sufficiently high temperatures each spin is completely randomly oriented. At sufficiently low temperatures all the spins become oriented along the same direction (i.e., Ferromagnetic). Let us approximate the heat capacity as a function of temperature T by

$$C(T) = \begin{cases} c_1 (T/T_0)^2 & 0 < T < T_0 \\ 0 & \text{otherwise} \end{cases}$$

where T_0 is a constant. Find the maximum value c_1 of the specific heat

(use entropy considerations).
(UC, Berkeley)

Solution:

$\frac{dS}{dT} =$

$\frac{C}{T}$

From $C = T \frac{dS}{dT}$, we have

$$S(T) - S(0) = \int_0^T \frac{C}{T} dT = c_1 \int_0^T \frac{(T/T_0)^2}{T} dT = c_1 \ln 2$$

On the other hand, we have from the definition of entropy $S(0) = 0$, $S(T) = Nk_B \ln 2$, hence

$Nk_B \ln 2 =$

$c_1 \ln 2$

$c_1 = Nk_B$

2011

The elasticity of a rubber band can be described in terms of a one-dimensional model of polymer involving N molecules linked together end-to-end. The angle between successive links is equally likely to be θ' or $180^\circ - \theta'$.

(a) Show that the number of arrangements that give an overall length of $L = 2md$ is given by $2N!$

$$g(N,m) = \binom{N}{m} + \binom{N}{N-m}$$

Statistical Physics 171

Indicate clearly the reasoning you used to get this result.

(b) For $m \ll N$, this expression becomes

$$g(N, m) \approx g(N, 0) \exp(-2m^2/N)$$

Find the entropy of the system as a function of L for $N \gg 1, L < Nd$.

(c) Find the force required to maintain the length L for $L \ll Nd$.

(d) Find the relationship between the force and the length, without using the condition in (c), i.e., for any possible value of L , but $N \gg 1$.

(UC, Berkeley)

N molecules

[$N = \text{constant}$]

$d = \text{length of one link}$

a

Fig. 2.3.

Solution:

angle then

$$N_+ - N_- = 2m,$$

Therefore $N_+ N_-$

$$N_+ = N/2 + m, N_- = N/2 - m.$$

2

(a) Assume that there are N_+ links of θ' angle and N_- links of $180'$

$$N_+ + N_- = N.$$

This corresponds to $N!/(N_+!N_-!)$ arrangements. Note that for every arrangement if the angles are reversed, we still get the overall length of $2md$. Thus

$$2N!$$

$$g = \binom{N}{N_+} \binom{N}{N_-}$$

(b) When $m \ll N$, $g(N, m) \approx g(N, 0) \exp(-2m^2/N)$, the entropy of the system becomes

$$kL^2$$

$$S = k \ln g(N, m) = k \ln g(N, 0) - 2 \sim d^2.$$

(c) From the thermodynamic relations $dU = TdS + fdL$ and $F =$

172 Problem 6 Solution on Thermodynamics 6 Statistical Mechanics

$$U - TS \text{ we obtain } dF = -SdT + fdL. \text{ Therefore } \left(\frac{\partial F}{\partial L}\right)_T = f = \frac{2kT}{d}.$$

$$kTL$$

$$Nd^2$$

$$f = -$$

As $f = 0$ when $L = 0$,

$$f = - \frac{kTL}{Nd^2}$$

$$Nd^2$$

(d) Consider only one link. When an external force f is exerted, the probability that the angle is θ' or $180'$ is proportional to ea or ePa respectively, where $a = fd/lcT$. The average length per link is therefore

The overall length of the polymer is then

$$L = Nl = Nd \tanh(fd/kT) .$$

2012

Consider a one-dimensional chain consisting of $n \gg 1$ segments as illustrated in the figure. Let the length of each segment be a when the long dimension of the segment is parallel to the chain and zero when the segment is vertical (i.e., long dimension normal to the chain direction). Each segment has just two states, a horizontal orientation and a vertical orientation, and each of these states is not degenerate. The distance between the chain ends is nx .

- Find the entropy of the chain as a function of x .
- Obtain a relation between the temperature T of the chain and the tension F which is necessary to maintain the distance nx , assuming the joints turn freely.
- Under which conditions does your answer lead to Hook's law?

(Princeton)

Statistical Physics 173

nx

Fig. 2.4.

Solution:

parallel to the chain; so the microscopic state number is

- When the length of the chain is nx , there are $rx = nx/a$ segments

$n!$

$m!(n-m)!$

$$n = C^n = \dots$$

We have

$$S = k \ln n$$

$n!$

$$= k \ln$$

$$(\frac{n!}{(n-E)!})$$

- Under the action of stress F , the energy difference between the vertical and parallel states of a segment is Fa . The mean length of a segment is

$$aeFa/kT$$

$$1 + eFa/kT$$

$$I =$$

so that

- At high temperatures,

$$L = nx = na(a + ag),$$

which is Hooke's Law.

2013

Consider an idealization of a crystal which has N lattice points and the same number of interstitial positions (places between the lattice points where atoms can reside). Let E be the energy necessary to remove an atom

174 Problems on Statistical Thermodynamics

from a lattice site to an interstitial position and let n be the number of atoms occupying interstitial sites in equilibrium.

- What is the internal energy of the system?
- What is the entropy S ? Give an asymptotic formula valid when
- In equilibrium at temperature T , how many such defects are there

(Princeton)

$n \gg 1$?

in the solid, i.e., what is n ? (Assume $n \gg 1$.)

Solution:

- Let U_0 be the internal energy when no atom occupies the interstitial sites. When n interstitial positions are occupied, the internal energy is then

$$U = U_0 + nE$$

(b) There are C_n^N ways of selecting n atoms from N lattice sites, and C_n^N ways to place them to N interstitial sites; so the microscopic state number is $\Omega = (C_n^N)^2$. Hence

$$N! / (n!(N-n)!)$$

$$S = k \ln \Omega = 2k \ln C_n^N$$

When $n \gg 1$ and $(N-n) \gg 1$, we have $\ln(n!) = n \ln n - n$, so that

$$S = 2k [N \ln N - n \ln n - (N-n) \ln(N-n)]$$

(c) With fixed temperature and volume, free energy is minimized at

From $F = U_0 + nE - TS$ and $dF/dn = 0$, we have equilibrium.

N

$$E = 2kT \ln \frac{N}{n}$$

2. MAXWELL-BOLTZMANN STATISTICS (2014-2062)

2014

(a) Explain Boltzmann statistics, Fermi statistics and Bose statistics, especially about their differences. How are they related to the indistinguishability of identical particles?

Statistical Physics 175

(b) Give as physical a discussion as you can, on why the distinction between the above three types of statistics becomes unimportant in the limit of high temperature (how high is high?). Do not merely quote formulas.

(c) In what temperature range will quantum statistics have to be applied to a collection of neutrons spread out in a two-dimensional plane with

the number of neutrons per unit area being $n = 10^{12}/\text{cm}^2$?

(SVNY, Buflafo)

Solution:

(a) *Boltzmann statistics*. For a localized system, the particles are distinguishable and the number of particles occupying a singlet quantum state is not limited. The average number of particles occupying energy level ϵ_l is

$$\langle n_l \rangle = \frac{w_l}{e^{\beta(\epsilon_l - \mu)}} ,$$

where w_l is the degeneracy of l -th energy level.

Fermi statistics. For a system composed of fermions, the particles are indistinguishable and obey Pauli's exclusion principle. The average number of particles occupying energy level ϵ_l is

$$\langle n_l \rangle = \frac{w_l}{e^{\beta(\epsilon_l - \mu)} + 1} .$$

Bose statistics. For a system composed of bosons, the particles are indistinguishable and the number of particles occupying a singlet quantum state is not limited. The average number of particles occupying energy level ϵ_l is

$$\langle n_l \rangle = \frac{w_l}{e^{\beta(\epsilon_l - \mu)} - 1} .$$

(b) We see from (a) that when $e^{\beta(\epsilon_l - \mu)} \gg 1$, or $e^{-\beta(\epsilon_l - \mu)} \ll 1$, three types of statistics vanishes.

, (n is the particle density), we see that

$$\frac{2mkT}{n^2/3h^2}$$

$$n^2/3h^2$$

the above condition is satisfied when $T \gg \frac{2mk}{3h^2}$. So the distinction among the three types of statistics becomes unimportant in the limit of high temperatures.

It can also be understood from a physical point of view. When $e^{\beta(\epsilon_l - \mu)} \gg 1$,

we have $q/wl \ll 1$, which shows that the average number of particles in

27rmk
176 Problem 3 d Solutions on Thermodynamics & Statistical Mechanics

any quantum state is much less than 1. The reason is that the number of microstates available to the particles is very large, much larger than the total particle number. Hence the probability for two particles to occupy the same quantum state is very small and Pauli's exclusion principle is satisfied naturally. As a result, the distinction between Fermi and Bose statistics vanishes.

(c) The necessity of using quantum statistics arises from the following two points. One is the indistinguishability of particles and Pauli's exclusion

principle, because of which $e^{\beta \epsilon} \ll 1$ is not very much smaller than 1 (degenerate). The other is the quantization of energy levels, i.e., $\Delta E \ll kT$, where ΔE is the spacing between energy levels, is not very much smaller than 1 (discrete).

h2

2.rrmkT

For a two-dimensional neutron system,

h2 - AE

kT 2mkTLZ

--

Taking $L \approx 1$ cm, we have $T \approx 10^8$ K. So the energy levels are quasicontinuous at ordinary temperatures. Hence the necessity of using quantum statistics is essentially determined by the strong-degeneracy condition

$$e^{-\beta \epsilon} \ll 1 \quad \text{or} \quad \frac{h^2}{2m} \ll kT$$

Substituting the quantities into the above expression, we see that quantum statistics must be used when $T \approx 10^8$ K.

Statistical Physics 177

Solution:

tions:

distinguished from one another.

a quantum state.

statistics.

(a) FD, as compared with MB, statistics has two additional assump-

1) The principle of indistinguishability: identical particles cannot be

2) Pauli's exclusion principle: Not more than one particle can occupy

In the limit of non-degeneracy, FD statistics gradually becomes MB

(b) $P(\epsilon)$ gives the number of particles in unit interval of energy or at energy level ϵ . Figure 2.5 gives rough plots of the energy distributions ((a)

MB, (b) FD).

$P(\epsilon) \approx \frac{1}{kT} e^{-\beta \epsilon}$

72 T1

E & F

(a) MB statistics (b) FD statistics

Fig. 2.5.

(c) According to MB statistics (or the principle of equipartition of energy), the contribution of an electron to the specific heat of a metal should be 1.5 kT. This is not borne out by experiments, which shows that the contribution to specific heat of free electrons in metal can usually be neglected except for the case of very low temperatures. At low temperatures the contribution of electrons to the specific heat is proportional to the temperature T. FD statistics which incorporates Pauli's exclusion principle can explain this result.

2016

State which statistics (classical Maxwell-Boltzmann; Fermi-Dirac; or Bose-Einstein) would be appropriate in these problems and explain why (semi-quantitatively):

- (a) Density of He4 gas at room temperature and pressure.
- (b) Density of electrons in copper at room temperature.
- (c) Density of electrons and holes in semiconducting Ge at room temperature (Ge band-gap is 1 eV).

(UC, Berkeley)

perature (Ge band-gap is 1 eV).

178 Problem 8 E / Solution 8 on Thermodynamics & Statistical Mechanics

Solution:

(a) Classical Maxwell-Boltzmann statistics is appropriate because

$\lambda \gg r$

$$n \lambda^3 \ll 1 \Rightarrow \left(\frac{h^3}{2\pi m k T} \right)^{3/2} n \ll 1$$

$\lambda \ll r$

(b) Fermi-Dirac statistics is appropriate because electrons are Fermions and the Fermi energy of the electron gas in copper is about 1 eV which is equivalent to a high temperature of 104K. At room temperature (low temperature), the electron gas is highly degenerate.

(c) Classical Maxwell-Boltzmann statistics is appropriate because at room temperature the electrons and holes do not have sufficient average energy to jump over the 1 eV band-gap in appreciable numbers.

2017

Show that $X = \exp(\mu/kT) = nVQ$ for an ideal gas, valid where $X \ll 1$; here μ is the chemical potential, n is the gas density and

$$VQ = \left(\frac{h^3}{2\pi m k T} \right)^{3/2} V$$

is the quantum volume. Even if you cannot prove this, this result will be useful in other problems.

(UC, Berkeley)

Solution:

In the approximation $X \ll 1$, Fermi-Dirac and Bose-Einstein statistics both tend to Maxwell-Boltzmann statistics:

The density of states of an ideal gas (spin states excluded) is

$D(\epsilon) = \frac{2\pi V}{h^3} (2m)^{3/2} \epsilon^{1/2}$

$D(\epsilon) = \frac{2\pi V}{h^3} (2m)^{3/2} \epsilon^{1/2}$

$$D(\epsilon) = \frac{2\pi V}{h^3} (2m)^{3/2} \epsilon^{1/2}$$

Therefore,

That is, $X = nVQ$.

Statistical Physics 179

2018

A long, thin (i.e., needle-shaped) dust grain floats in a box filled with

gas at a constant temperature T . On average, is the angular momentum vector nearly parallel to or perpendicular to the long axis of the grain?

Explain.

(MITI)

Solution:

Let the long axis of the grain coincide with the z-axis. The shape of the grain indicates that the principal moments of inertia satisfy $I_x < I_y, I_z$.

When thermal equilibrium is reached, we have

$$-I_x \dot{\phi} = -I_y \dot{\theta} = -I_z \dot{\psi} = 2kT$$

so that $I_x \dot{\phi} = (kT) \dot{\theta} = (kT) \dot{\psi}$. Therefore

So the angular momentum vector is nearly perpendicular to the long axis of the grain.

2019

A cubically shaped vessel 20 cm on a side contains diatomic H_2 gas at a temperature of 300 K. Each H_2 molecule consists of two hydrogen atoms

with mass of 1.66×10^{-27} g each, separated by 10^8 cm. Assume that the gas behaves like an ideal gas. Ignore the vibrational degree of freedom.

- (a) What is the average velocity of the molecules?
- (b) What is the average velocity of rotation of the molecules around an axis which is the perpendicular bisector of the line joining the two atoms (consider each atom as a point mass)?
- (c) Derive the values expected for the molar heat capacities C_v and C_p for such a gas.

(Columbia)

180 Problems in Statistical Thermodynamics and Statistical Mechanics

Solution:

have

(a) The number of the translational degrees of freedom is 3. Thus we

$$v_{rms} = \sqrt{3kT/M}$$

(b) The number of the rotational degrees of freedom is 2. Hence

1/2

$$I \omega^2 = kT$$

1/2

where $I = m \cdot r^2 = 2m \cdot r^2$ is the moment of inertia of the molecules

Here, m is the mass of the atom H and r is the distance between the two hydrogen atoms. Thus we get

$$\omega = \sqrt{kT / (2m \cdot r^2)}$$

(c) The molar heat capacities are respectively

5

7

$$C_v = \frac{5}{2} R = 20.8 \text{ J/mol} \cdot \text{K}$$

2020

The circuit shown is in thermal equilibrium with its surroundings at a temperature T . Find the classical expression for the root mean square current through the inductor.

(MIT)

Fig. 2.6.

Statistical Physics 181

Solution:

Fluctuations in the motion of free electrons in the conductor give rise to fluctuation currents. If the current passing through the inductor is $I(t)$,

then the average energy of the inductor is $\overline{W} = \frac{1}{2} L \overline{I^2}$, where $\overline{I^2}$ is the mean square current. According to the principle of equipartition of energy, we

have

$\frac{1}{2} L \overline{I^2} = kT$.

Hence

$\overline{W} = kT$.

2021

Energy probability.

Find and make careful sketch of the probability density, $p(E)$, for the energy E of a single atom in a classical non-interacting monatomic gas in thermal equilibrium.

(MIT)

Solution:

When the number of gas atoms is very large, we can represent the states of the system by a continuous distribution. When the system reaches thermal equilibrium, the probability of an atom having energy E is proportional to $\exp(-E/kT)$, where $E = p^2/2m$, p being the momentum of the atom.

So the probability of an atom lying between p and $p + dp$ is

$$A \exp(-p^2/2mkT) d^3p .$$

From

$$\int_0^\infty \int_0^\infty \int_0^\infty \exp(-p^2/2mkT) d^3p = 1 ,$$

$$A = \left(\frac{2\pi m k T}{h^2} \right)^{3/2} .$$

we obtain

Therefore,

2024

Consider a glass in which some fraction of its constituent atoms may occupy either of two slightly different positions giving rise to two energy levels $\mathbf{A}; > 0$ and $-\mathbf{A}$, for the i th atom.

(a) If each participating atom has the same levels \mathbf{A} and $-\mathbf{A}$, calculate the contribution of these atoms to the heat capacity. (Ignore the usual

Debye specific heat which will also be present in a real solid.)

(b) If the glass has a random composition of such atoms so that all values of A_i are equally likely up to some limiting value $A_0 > 0$, find the behavior of the low temperature heat capacity, i.e., $kT \ll A_0$. (Definite integrals need not be evaluated provided they do not depend on any of the parameters.)

(Princeton)

Solution:

(a) The mean energy per atom is $\bar{E} = A \tanh \left(\frac{A}{kT} \right)$. Its contribution to the specific heat is

$$C_v = \frac{d\bar{E}}{dT}$$

$$C_v = -4k \left(\frac{A}{kT} \right)^2 \frac{d}{dT} \left(\frac{e^{A/kT} + e^{-A/kT}}{2} \right)$$

Summing up the terms for all such atoms, we have

$$C_v = N \frac{d\bar{E}}{dT}$$

$$C_v = 4Nk \left(\frac{A}{kT} \right)^2 \frac{d}{dT} \left(\frac{e^{A/kT} + e^{-A/kT}}{2} \right)$$

(b) The contribution to the specific heat of the i th atom is

$$C_{vi} = \frac{dE_i}{dT}$$

$$C_{vi} = 4k \left(\frac{A_i}{kT} \right)^2 \frac{d}{dT} \left(\frac{e^{A_i/kT} + e^{-A_i/kT}}{2} \right)$$

When $kT \ll A_i$, we have

Statistical Physics 185

Summing up the terms for all such atoms, we have

where $\rho(A)$ is the state density of distribution of A_i .

2025

The three lowest energy levels of a certain molecule are $E_1 = 0$, $E_2 = \epsilon$, $E_3 = 10\epsilon$. Show that at sufficiently low temperatures (how low?) only levels E_1 , E_2 are populated. Find the average energy \bar{E} of the molecule at temperature T . Find the contributions of these levels to the specific heat per mole, C_v , and sketch C_v as a function of T .

(Wisconsin)

Solution:

levels for low temperatures.

according to the Boltzmann statistics, we have

We need not consider energy levels higher than the three lowest energy

Assuming the system has N particles and

$$N_1 + N_2 + N_3 = N,$$

hence

$$N_3 = 1 + e^{-\epsilon/kT} + e^{-10\epsilon/kT}$$

$$N_3 = 1 + e^{-\epsilon/kT} + e^{-10\epsilon/kT}$$

When $N_3 \ll 1$, there is no occupation at the energy level E_3 . That is, when

$T \ll T_c$, only the E_1 and E_2 levels are occupied, where T_c satisfies

If $N \gg 1$, we have

$$\ln N = \ln N_1 + \ln N_2 + \ln N_3$$

$$\ln N = \ln N_1 + \ln N_2 + \ln N_3$$

$$T_c = \frac{\epsilon}{k \ln 2}$$

186 Problems in Solution, on Thermodynamics and Statistical Mechanics

The average energy of the molecule is

The molar specific heat is

where

For high temperatures, $kT \gg \epsilon$,

2026

Given a system of two distinct lattice sites, each occupied by an atom whose spin ($s = 1$) is so oriented that its energy takes one of three values $\epsilon = 1, 0, -1$ with equal probability. The atoms do not interact with each other. Calculate the ensemble average values and χ for the energy U of the system, assumed to be that of the spins only.

(UC, Berkeley)

Statistical Physics 187

Solution:

For a single atom, we have

For the system, we have

Since $\chi = \frac{1}{kT} \left(\frac{\partial U}{\partial N} \right)$ it follows

2027

Obtain the temperature of each system:

(a) 6.0×10^{23} atoms of helium gas occupy 2.0 litres at atmospheric pressure. What is the temperature of the gas?

(b) A system of particles occupying single-particle levels and obeying Maxwell-Boltzmann statistics is in thermal contact with a heat reservoir at temperature T . If the population distribution in the non-degenerate energy levels is as shown, what is the temperature of the system?

Energy (eV) population

30.1×10^{-3} 3.1%

21.5×10^{-3} 8.5%

12.9×10^{-3} ~ 23%

4.3×10^{-3} 63%

(c) In a cryogenic experiment, heat is supplied to a sample at the constant rate of 0.01 watts. The entropy of the sample increases with time as shown in the table. What is the temperature of the sample at $t = 500$ sec?

Time: 100 200 300 400 500 600 700 (sec)

Entropy: 2.30 2.65 2.85 3.00 3.11 3.20 3.28 (J/K)

(UC, Berkeley)

188 Problems in Statistical Thermodynamics and Statistical Mechanics

Solution:

(a) Using the equation of state for an ideal gas, we get

$$T = \frac{pV}{nk} = 241 \text{ K}$$

(b) The population distribution is given by

Therefore

Using the given n_1 and n_2 , we get T as follows:

$$99.2; 99.5; 99.0; 99.5; 100.2; 98.8 \text{ K}$$

The mean value is $T = 99.4 \text{ K}$.

(c) The rate of heat intake is $\dot{Q} = T \dot{S}$, giving

$$\frac{dQ}{dt} = T \frac{dS}{dt}$$

$$\frac{dQ}{dt} = T \frac{dS}{dt}$$

$$T = \frac{dQ}{dS}$$

(%)

dS

dt

We estimate - by the middle differential at $t = 500s$, and get
 $= 1.0 \times 10^{-3} J/sec.K$

@ = (3.20 - 3.00)

dt 600 - 400

Therefore $T = 10K$.

2028

Assume that the reaction $H^+ + p + e$ occurs in thermal equilibrium at
 $T = 4000 K$ in a very low density gas (no degeneracy) of each species with
overall charge neutrality.

(a) Write the chemical potential of each gas in terms of its number
density $[H]$, $[p]$, or $[e]$. For simplicity you may ignore the spectrum of
Statistical Physics 189

excited bound states of H and consider only the ground state. Justify this
assumption.

(b) Give the condition for thermal equilibrium and calculate the equilibrium
value of $[e]$ as a function of $[H]$ and T .

(c) Estimate the nucleon density for which the gas is half-ionized at T
 $= 4000 K$. (Note that this is an approximate picture of the universe at a
redshift $z = 103$.)

(UC, Berkeley)

Solution:

(a) From Boltzmann statistics, we have for an ideal gas without spin

$$n = \frac{2 \pi m k T / h^2}{\lambda^3} e^{-\mu/kT}$$

Both the proton and electron have spin 1/2, therefore

$$[p] = 2 \left(\frac{2 \pi m_p k T}{h^2} \right)^{-3/2} e^{-\mu_p/kT}$$

$$[e] = 2 \left(\frac{2 \pi m_e k T}{h^2} \right)^{-3/2} e^{-\mu_e/kT}$$

For the hydrogen atom, p and e can form four spin configurations with
ionization energy E_d . Hence

$$[H] = 4 \left(\frac{2 \pi m_H k T}{h^2} \right)^{-3/2} e^{-\mu_H/kT} = \frac{4 e^{-\mu_H/kT}}{e^{-\mu_p/kT} e^{-\mu_e/kT}}$$

The chemical potentials μ_p , μ_e and μ_H are given by the above relations with
the number densities.

(b) The equilibrium condition is $\mu_H = \mu_p + \mu_e$. Note that as $\mu_p \approx \mu_e \approx \mu_H$
and $[e] = [p]$ we have

$$[e] = \frac{m_p}{m_e} \left(\frac{2 \pi m_e k T}{h^2} \right)^{-3/2} e^{-\mu_p/kT} e^{-\mu_e/kT} = \frac{m_p}{m_e} \left(\frac{2 \pi m_e k T}{h^2} \right)^{-3/2} e^{-\mu_H/kT}$$

(c) When the gas is half-ionized, $[e] = [p] = [H] = n$. Hence

$$n = \left(\frac{2 \pi m_e k T}{h^2} \right)^{-3/2} e^{-\mu_p/kT} e^{-\mu_e/kT} = 3.3 \times 10^{16} n^{-1/2}$$

2029

A piece of metal can be considered as a reservoir of electrons; the work
function (energy to remove an electron from the metal) is 4 eV. Considering

190 Problems 6 Solutions on Thermodynamics 6 Statistical Mechanics

only the 1s orbital (which can be occupied by zero, one, or two electrons)
and knowing that the hydrogen atom has an ionization energy of 13.6 eV
and an electron affinity of 0.6 eV, determine for atomic hydrogen in chemical
equilibrium at $T = 300 K$ in the vicinity of a metal the probabilities of
finding H^+ , H^0 and H^- . Give only one significant figure.

What value of the work function would give equal probabilities to H^0
and H^- ?

(UC, Berkeley)

Solution:

We have (see Fig. 2.8)

$e + H^+ \sim H$,

$e + H \rightleftharpoons H^-$.

Fermi sea

Fig. 2.8.

The chemical potential of the electron gas is $\mu_e = -W$. From classical statistics, we can easily obtain

where the factor 2 arises from the internal degrees of freedom of spin. For the hydrogen atom, electron and proton spins can have four possible spin states, hence

Statistical Physics 191

For H^- , both electrons are in their ground state with total spin 0 (singlet), as the space wave function is symmetric when the particles are interexchanged.

Therefore, the spin degrees of freedom of H^- correspond only to the two spin states of the nucleon; hence

The conditions for chemical equilibrium are so that

Thus, the relative probabilities of finding H^+ , H^0 and H^- are

If $\frac{P_{H^+}}{P_{H^-}} = \frac{P_{H^0}}{P_{H^-}}$, or $\frac{[H^+]}{[H^0]} = 1$, we have

$$W = -\mu_e = -\epsilon_a + kT \ln 2 \approx 0.6 \text{ eV}.$$

2030

The potential energy V between the two atoms ($m \approx 1.672 \times 10^{-27} \text{ g}$) in a hydrogen molecule is given by the empirical expression

$$V = D \left\{ e^{-2a(r-r_0)} - 2e^{-a(r-r_0)} \right\}.$$

where r is the distance between the atoms.

$$D = 7 \times 10^{-19} \text{ erg},$$

192 Problems in Statistical Mechanics

$$a = 2 \times 10^8 \text{ cm}^{-1}$$

$$r_0 = 8 \times 10^{-10} \text{ cm}.$$

Estimate the temperatures at which rotation (TR) and vibration (TV) begin to contribute to the specific heat of hydrogen gas. Give the approximate values of C_V and C_P (the molar specific heats at constant volume and at constant pressure) for the following temperatures:

Neglect ionization and dissociation.

Solution:

librium distance. From

$$T_1 = 25 \text{ K}, T_2 = 250 \text{ K}, T_3 = 2500 \text{ K}, T_4 = 10000 \text{ K}.$$

(UC, Berkeley)

The average distance between the two atoms is approximately the equi-

$$\left(\frac{\partial}{\partial r} \right)_{r=d} = 0,$$

we obtain $d = r_0$. The frequency of the radial vibration of the two atoms is ν

where $\mu = m/2$ is the reduced mass and so

$$W = \frac{1}{2} k \nu^2.$$

The characteristic energy of the rotational level is then

$$= \frac{1}{2} k T_R = \frac{1}{2} k \frac{h^2}{8\pi^2 \mu r^2}.$$

The characteristic energy of vibration is $k T_V = W$, then

Statistical Physics 193

Thus, rotation begins to contribute to the specific heat at $T = 75 \text{ K}$, and

vibration does so at $T = 6250 \text{ K}$.

When $T = 25 \text{ K}$, only the translational motion contributes to C , then

35

$$C_v = -2R = 12.5 \text{ J/K}, C_p = -R = 20.8 \text{ J/K}$$

When $T = 250 \text{ K}$, only translation and rotation contribute to C , then

57

2

$$C_v = iR = 20.8 \text{ J/K}, C_p = -R = 29.1 \text{ J/K}.$$

When $T = 2500 \text{ K}$, the result is the same as for $T = 250 \text{ K}$.

When $T = 10000 \text{ K}$, vibration also contributes to C , then

$$C_p = 7R = 29.1 \text{ J/K}, C_v = 5R = 37.4 \text{ J/K}.$$

v. 2 p. 2

2051

Derive an expression for the vibrational specific heat of a diatomic gas as a function of temperature. (Let $h\nu/k = \theta$). For full credit start with an expression for the vibrational partition function, evaluate it, and use the result to calculate C_{vib} .

Describe the high and low T limits of C_{vib} .

(MIT)

Solution:

The vibrational energy levels of a diatomic gas are

$$E_n = h\nu(n + 1/2), n = 0, 1, 2, \dots$$

The partition function is

where $z = e^{-\beta h\nu/2} / (1 - e^{-\beta h\nu})$. The free energy of 1 mole of the gas is

(c) The equation of state is

$$p = -N \frac{\partial \ln Z}{\partial V} = -N \frac{\partial}{\partial V} \left(\frac{1}{2} \ln \frac{2\pi m}{h^2} \right) = \frac{NkT}{2V}$$

where p is the pressure.

(d) The fraction of particles in the m -th level is

2034

The molecules of a certain gas consist of two different atoms, each with zero nuclear spin, bound together. Measurements of the specific heat of this material, over a wide range of temperatures, give the graph shown below.

Statistical Physics 197

(The values marked on the vertical scale correspond to the height of the curve in each of the 'plateau' regions.)

regions: above T_3 ; between T_2 and T_3 ; between T_1 and T_2 ; below T_1 ,

(a) Account for each of the different results found in the temperature

(b) Given that the first excited state of the rotational spectrum of

this molecule is at an energy kT_e above the ground rotational state, and

$T_e = 64 \text{ K}$, calculate from basic theory the rotational contribution to the specific heat capacity of this gas at 20 K , at 100 K , at 300 K .

(UC, Berkeley)

Solution:

(a) When $T > T_3$, the translational, rotational and vibrational motions are all excited, and $C_v = 7k/2$. When $T_2 < T < T_3$, the vibrational motion

is not excited and $C_v = 5k/2$. When $T_1 < T < T_2$, only the translational motion contributes to the specific heat and $C_v = 3k/2$. When $T < T_1$, a

phase transition occurs, and the gas phase no longer exists.

(b) When $T = 20 \text{ K}$, neglect the higher rotational energy levels and consider only the ground state and the 1st excited state. We have

When $T = 100$ K, consider the first two excited states and we have
 When $T = 300$ K, all the rotational energy levels are to be considered and
 $C_v = 1.0$ k

198 Problem 3 *Solution on Thermodynamic & Statistical Mechanics*
2035

The quantum energy levels of a rigid rotator are

$$E_j = j(j+1) \frac{h^2}{8\pi^2 I} = \frac{h^2}{8\pi^2 I} j(j+1),$$

where $j = 0, 1, 2, \dots$. The degeneracy of each level is $g_j = 2j + 1$.

- (a) Find the general expression for the partition function, and show that at high temperatures it can be approximated by an integral.
- (b) Evaluate the high-temperature energy and heat capacity.
- (c) **Find** the low-temperature approximations to Z , U and C_v .

(SUNY, Buffalo)

Solution:

(a) The partition function is

$$Z = \sum_{j=0}^{\infty} g_j e^{-\beta E_j} = \sum_{j=0}^{\infty} (2j+1) e^{-\beta \frac{h^2}{8\pi^2 I} j(j+1)}$$

(b) At high temperatures $\beta \frac{h^2}{8\pi^2 I} \ll 1$, where
 Hence

$$Z \approx \int_0^{\infty} (2j+1) e^{-\beta \frac{h^2}{8\pi^2 I} j(j+1)} dj = \frac{8\pi^2 I}{h^2} kT$$

The internal energy is

$$U = kT^2 \ln Z = kT \left(\ln \frac{8\pi^2 I}{h^2} kT \right)$$

Statistical Physics 199

(c) For low temperatures, we need only take the first two terms of Z ,

$$i.e., Z \approx 1 + 3e^{-\beta \frac{h^2}{8\pi^2 I}}, \text{ where } \beta = \frac{1}{kT}$$

so

2036

The quantum energy levels of a rigid rotator are

$$E_j = j(j+1) \frac{h^2}{8\pi^2 I} = \frac{h^2}{8\pi^2 I} j(j+1),$$

where $j = 0, 1, 2, \dots, m$ and a and b are positive constants. The degeneracy of each level is $g_j = 2j + 1$.

- (a) Find the general expression for the partition function Z .
- (b) Show that at high temperatures it can be approximated by an integral.
- (c) Evaluate the high-temperature energy U and heat capacity C_v .
- (d) Also, find the low-temperature approximations to Z , U and C_v .

(SUNY, Buffalo)

Solution:

(a) The partition function is

where,

$$\beta = \frac{1}{kT}$$

200 Problems *Solution on Thermodynamics & Statistical Mechanics*

(b) At high temperatures $\beta \frac{h^2}{8\pi^2 I} \ll 1$ and $\exp[-\beta \frac{h^2}{8\pi^2 I} j(j+1)]$ changes slowly as j changes, so that we can think of $(2j+1) \exp[-\beta \frac{h^2}{8\pi^2 I} j(j+1)]$ as

a continuous function of j . Let $x = j(j+1)$, then $dx = 2j+1$, and we can write z as an integral:

(c) At high temperatures, the internal energy is

a

aB

$$U = -\ln z = kT$$

The heat capacity is

$$C_v = k$$

(d) At low temperatures, we have $T \ll \theta$, and $\exp[-j(j+1)/T]$ is very small. We need only take the first two terms of z , so

2037

The energy levels of a three-dimensional rigid rotor of moment of inertia I are given by

$$E_{J,M} = \frac{h^2 J(J+1)}{2I}$$

where $J = 0, 1, 2, \dots$; $M = -J, -J+1, \dots, J$. Consider a system of N rotors:

(a) Using Boltzmann statistics, find an expression for the thermodynamic

(b) Under what conditions can the sum in part (a) be approximated

by an integral? In this case calculate the specific heat C_v of the system.

(Wisconsin)

Statistical Physics 201

Solution:

(a) The partition function of the system is

$$z = \sum_{J=0}^{\infty} (2J+1) \exp[-h^2 J(J+1)/2IkT]$$

The internal energy is

$$U = -kT \ln z$$

$$dU = NkT^2$$

$$C_v = Nk$$

(b) In the limit of high temperatures, $kT \gg h^2/2I$, and the above sum

can be replaced by an integral. Letting $x = J(J+1)$, we have

$$z \approx \int_0^{\infty} e^{-x/2IkT} (2x+1) dx = 2IkT$$

$$U = NkT$$

Thus the molar specific heat is $C_v = Nk = R$.

2038

Consider a heteronuclear diatomic molecule with moment of inertia I . In this problem, only the rotational motion of the molecule should be considered.

(a) Using classical statistical mechanics, calculate the specific heat

$C_v(T)$ of this system at temperature T .

(b) In quantum mechanics, this system has energy levels

$$E_j = \frac{h^2}{2I} j(j+1), \quad j = 0, 1, 2, \dots$$

$$E_j = \frac{h^2}{2I} (j+1/2)^2, \quad j = 0, 1, 2, \dots$$

- 21

Each j level is $(2j+1)$ -fold degenerate. Using quantum statistics, derive expressions for the partition function z and the average energy $\langle E \rangle$ of this

202 PmMems d Sdution on Thermodynamics d Statistical Mechonica

system, as a function of temperature. Do not attempt to evaluate these expressions.

(c) By simplifying your expressions in (b), derive an expression for the specific heat $C(T)$ that is valid at very low temperatures. In what range of temperatures is your expression valid?

(d) By simplifying your answer to (b), derive a high temperature approximation to the specific heat $C(T)$. What is the range of validity of your approximation?

(Princeton)

Solution:

(a) For a classical rotator, one has

$$E = \frac{1}{2} I \omega^2$$

21

$$Z = \int_0^\infty e^{-\beta E} g(E) dE, \quad g(E) = \frac{2\pi I}{h^2} \omega$$

$$\ln Z(E) = -\ln Z = -\frac{E}{kT}$$

ap @

Thus $C(T) = k$.

(b) In quantum statistical mechanics,

@h²

(c) In the limit of low temperatures, $\beta h^2 \gg 1$, or $\beta h^2 \gg kT$, so only **21 21**

Statistical Physics 203

the first two terms $j = 0$ and $j = 1$ are important. Thus

$$Z = 1 + 3 \exp\left(-\frac{2h^2}{8kT}\right)$$

$$\ln Z \approx \ln\left(1 + \frac{3h^2}{8kT}\right)$$

$$E = -kT \ln Z$$

$$C = k \left[\frac{3h^2}{8kT} \right]$$

Hence

2

$$= 3k$$

(&)²

$$\left[3 + \exp\left(-\frac{2h^2}{8kT}\right) \right]^{-1}$$

h²

21

(d) In the limit of high temperatures, $\beta h^2 \ll 1$ or $kT \gg \beta h^2$, so the **21** sum can be replaced by an integral, that is,

21

$$Z = \int_0^\infty e^{-\beta E} g(E) dE$$

$$\ln Z = -\ln Z = -\frac{E}{kT}$$

aB

Thus $C(T) = k$.

2039

At the temperature of liquid hydrogen, **20.4K**, one would expect molecular

H₂ to be mostly (nearly 100%) in a rotational state with zero angular momentum. In fact, if **H₂** is cooled to this temperature, it is found that

more than half is in a rotational state with angular momentum h . **A** catalyst

must be used at **20.4K** to convert it to a state with zero rotational angular momentum. Explain these facts.

(Columbia)

204 Problems and solutions on Thermodynamics and Statistical Mechanics

Solution:

The hydrogen molecule is a system of fermions. According to Pauli's exclusion principle, its ground state electron wave function is symmetric. So if the total nuclear spin I is zero, the rotational quantum number of angular momentum must be even and the molecule is called parahydrogen. If the total nuclear quantum spin I is one, the rotational quantum number of angular momentum must be odd and it is called orthohydrogen. Since the spin I has the $2I + 1$ orientation possibilities, the ratio of the number of orthohydrogen molecules to the number of parahydrogen molecules is **3:1** at sufficiently high temperatures. As it is difficult to change the total nuclear spin when hydrogen molecules come into collision with one another, the ortho- and parahydrogen behave like two independent components. In other words, the ratio of the number of orthohydrogen molecules to that of parahydrogen molecules is quite independent of temperature. So there are more orthohydrogen molecules than parahydrogen molecules even in the liquid state. A catalyst is needed to change this.

2040

A gas of molecular hydrogen H_2 , is originally in equilibrium at a temperature of 1,000 K. It is cooled to 20K so quickly that the nuclear spin states of the molecules do not change, although the translational and rotational degrees of freedom do readjust through collisions. What is the approximate internal energy per molecule in terms of temperature units K?

Note that the rotational part of the energy for a diatomic molecule is

$A I(I + 1)$ where I is the rotational quantum number and $A = 90K$ for H_2 .

Vibrational motion can be neglected.

(MIT)

Solution:

Originally the temperature is high and the para- and orthohydrogen molecules are in equilibrium in a ratio of about **1:3**. When the system is quickly cooled, for a rather long period the nuclear spin states remain the same. The ratio of parahydrogen to orthohydrogen is still **1:3**. Now the para- and orthohydrogen are no longer in equilibrium but, through collisions, each component is in equilibrium by itself. At the low temperature

of 20 K, $\exp(-PA) \ll \exp(-90/20) \ll 1$, so that each is in its ground state.

Statistical Physics 205

--

Thus $E_{r,p} = 0$, $E_{r,o} = A (1 + 1) = 2A = 180 K$, giving

From equipartition of energy, we have

-3

$$E_t = \frac{3}{2} kT = 30 K .$$

2

The average energy of a molecule is

-

$$E = E_t + E_r = 165 K .$$

2041

The graph below shows the equilibrium ratio of the number of orthohydrogen molecules to the number of parahydrogen molecules, as a function

of the absolute temperature. The spins of the protons are parallel in orthohydrogen and antiparallel in parahydrogen.

(a) Exhibit a theoretical expression for this ratio as a function of the temperature.

(b) Calculate the value of the ratio for 100 K, corresponding to the separation of the protons in the hydrogen

(UC, Berkeley)

point F on the graph.

molecule is **0.7415k**

Fig. 2.11.

206 Problems & solutions on Thermodynam'ed & Statisticd Mechanics

Solution:

(a) The moment of inertia of the hydrogen molecule is and its rotational energy level is

with degeneracy $(2J + 1), J = 0, 1, 2, \dots$. For ortho-H, $J = 1, 3, 5, \dots$; for

para-H, $J = 0, 2, 4, 6, \dots$. Thus in hydrogen molecules, the ratio of the number of ortho-H to that of para-H is

where the coefficient 3 results from spin degeneracy and

(b) When $T = 100$ K, $A = 0.88$, since as J increases the terms in the summations decrease rapidly, we need consider only the first two terms.

Hence

$e^{-2} + \frac{1}{3}e^{-12}$

$1 + 5e^{-GA}$

$f = 3 = 1.52$

Statistical physics 207

2042

In hydrogen gas at low temperatures, the molecules can exist in two states: proton spins parallel (orthohydrogen) or anti-parallel (parahydrogen). The transition between these two molecular forms is slow. Experiments performed over a time scale of less than a few hours can be considered as if we are dealing with two separate gases, in proportions given by their statistical distributions at the last temperature at which the gas was allowed to come to equilibrium.

(a) Knowing that the separation between protons in a hydrogen molecule is 7.4×10^{-10} cm, estimate the energy difference between the ground state and the first excited rotational state of parahydrogen. Use degrees Kelvin as your unit of energy. Call this energy ϵ_0 , so that errors in (a) do not propagate into the other parts of the question.

(b) Express the energy difference between the ground and first excited rotational states of orthohydrogen, ϵ_1 , in terms of ϵ_0 . In an experiment to measure specific heats, the gas is allowed to come to equilibrium at elevated temperature, then cooled quickly to the temperature at which specific heat is measured. What will the constant-volume molar specific heat be at:

(c) temperatures well above ϵ_0 and ϵ_1 , but not high enough to excite

(d) temperatures much below ϵ_0 and ϵ_1 [include the leading temperature-dependent term]?

(e) $T = \epsilon_0/2$?

vibrational levels?

(ZJC, Berkeley)

Solution:

The hydrogen nucleus is a fermion. The total wave function including the motion of the nucleus is antisymmetric. The symmetry of the total wave function can be determined from the rotational and spin wave functions.

For orthohydrogen, the spin wave function is symmetric when the nuclei are interchanged. Therefore, its rotational part is antisymmetric, i.e. J is odd. Similarly, for parahydrogen, J i.e. even. Then we have

, $l = 1, 3, 5, \dots$

, $l = 0, 2, 4, \dots$

$$l(l+1)\hbar^2$$

$$l(l+1)\hbar^2$$

$$2l$$

$$2l$$

ortho-hydrogen: $E_l =$

para-hydrogen: $E_l =$

where I is the moment of inertia of the nucleus about the center of separation.

Problems 4 Solutions on Thermodynamics 4 Statistical Mechanics

tion.

m

(a) $I = \frac{1}{2} m d^2$,

$$I = \frac{1}{2} m d^2$$

$$I = \frac{1}{2} m d^2$$

$$k_B T =$$

$$2$$

$$6h$$

$$m d^2$$

then $k_B T = 7.3 \times 10^{-3} \text{ J}$, $T = 530 \text{ K}$.

As the hydrogen gas had reached thermal equilibrium at high temperature before the experiment, the ratio of the number of the para- to that of the ortho-hydrogen in the experiment is 1:3, which is the ratio of the degrees of freedom of the spins.

(c) When $T \gg 600$, the rotational energy levels are completely excited.

From equipartition of energy, $E = nkT$, or $C_v = nk$, where n is the total number of the hydrogen molecules. (Note that here we only consider the specific heat associated with rotation.)

(d) When $T \ll 600$, there are almost no hydrogen atoms in the highly excited states. Therefore, we consider only the 1st excited state for para- and ortho-hydrogen. Noting the degeneracy of the energy levels, we have for ortho-hydrogen

Similarly we have for para-hydrogen

2

$$C_{ip} = n_p k_B \left(\frac{5}{2} - \frac{e^{-\epsilon_0/T}}{1 + e^{-\epsilon_0/T}} \right)$$

Note that

$$3/2$$

$$n_o = z_n, n_p = i n_o$$

Statistical Physics 209

(e) When $T = 600/2$, the partition functions for ortho- and para-hydrogen are

where $X = \frac{h^2}{4I} = \frac{h^2}{4 \cdot \frac{1}{2} m d^2} = \frac{h^2}{2 m d^2}$. It does not appear possible to solve these and calculate C_v accurately, but we can estimate them using the approximate results of (d).

2043

Molecular hydrogen is usually found in two forms, ortho-hydrogen ("parallel" nuclear spins) and para-hydrogen ("anti-parallel" nuclear spins).

(a) After coming to equilibrium at "high" temperatures, what fraction of H_2 gas is para-hydrogen (assuming that each variety of hydrogen is mostly in its lowest energy state)?

(b) At low temperatures ortho-hydrogen converts mostly to para-hydrogen. Explain why the energy released by each converting molecule is much

larger than the energy change due to the nuclear spin flip.

(was cons in)

Solution:

(a) For the two kinds of diatomic molecules of identical nuclei, the vibrational motion and the degeneracy of the lowest state of electron are the same for both while their rotational motions are different. The identical nuclei being fermions, antisymmetric nuclear spin states are associated with rotational states of even quantum number l , and symmetric nuclear spin states are associated with rotational states of odd quantum number l (the reverse of bosons). Thus

where s is the half-integer spin of a nucleon (for the hydrogen nucleus, $s = 1/2$), $s(2s+1)$ is the number of antisymmetric spin states and $(s+1)(2s+1)$ is the number of symmetric spin states.

210 Problems 8 Sokolov on Thermodynamics & Statistical Mechanics

is the number of symmetric spin states.

where $B = h^2/8\pi^2 I$, I being the rotational moment of inertia. For high temperatures, we have $Z_{para} = Z_{ortho}$, and $n_{para}/n_{H_2} = 1/4$. According to the condition given in the problem (the temperature is not too high), only states $l = 0$ and $l = 1$ exist. The fraction of parahydrogen is then

(b) When $T \ll 6$, orthohydrogen changes into parahydrogen. The energy corresponding to the change in nuclear spin direction is the coupling energy of the magnetic dipoles of the nuclei and the electrons $A E_s j_n$ 10^8 Hz. Since the rotational states are related to the nuclear spin states, the rotational states change too, the corresponding energy change being

$$w_{l \rightarrow l'} = \frac{h^2}{8\pi^2 I} l(l+1) - \frac{h^2}{8\pi^2 I} l'(l'+1)$$

$$A E_s j_n$$

$$A E_s j_n$$

When orthohydrogen converts to parahydrogen, the total energy change is

$$\Delta E = A E_s j_n + A E_s j_n$$

$$A E_s j_n$$

2044

A 14 N nucleus has nuclear spin $I = 1$. Assume that the diatomic molecule N_2 can rotate but does not vibrate at ordinary temperatures and ignore electronic motion. Find the relative abundances of the ortho- and para-molecules in a sample of nitrogen gas. (Ortho = symmetric spin state; Para = antisymmetric spin state). What happens to the relative abundance as the temperature is lowered towards absolute zero? (Justify your answers!)

(SVNY, Buffalo)

Statistical Physics 211

Solution:

The wave function of N_2 is symmetric as 14 N is a boson. The spin wave functions of N_2 consist of six symmetric and three antisymmetric functions. We know that the rotating wave function is symmetric when the spin wave function is symmetric, and the rotating wavefunction is antisymmetric when the spin wave function is antisymmetric. Hence, the partition function of ortho- N_2 is

and I is the rotational moment of inertia of N_2 . Similarly, A_2 where $B = -2kT$

$$Z_{para} = 3(2l+1)e^{-or'(l+1)/T}$$

$$l = 1, 3, 5, \dots$$

As $B/T \ll 1$ at ordinary temperatures, the sums can be replaced by integrals:

$$3T$$

$$e^{-erx/T} dx = -$$

$$20,$$

Therefore, the relative abundance is given by
 At equilibrium, $n_{ortho} = n_{para}$, the above ratio is 2.

$n_{ortho}/n_{para} = \exp[-E_{ortho}/kT] / \exp[-E_{para}/kT] \ll 1$. Hence

When the temperature is lowered towards the absolute zero, we have
 The relative abundance is

$$n_{ortho} = \left(\frac{1}{2} \right) \exp(2E_{para}/kT)$$

n_{para}

212 Problems 8 Solutions on Thermodynamics & Statistical Mechanics

When $T \rightarrow 0$, the relative abundance $\rightarrow \infty$. All the para-molecules become ortho-molecules.

2045

(a) Write down a simple expression for the internal part of the partition function for a single isolated hydrogen atom in very weak contact with a reservoir at temperature T . Does your expression diverge for $T = 0$, for $T \neq 0$?

(b) Does all or part of this divergence arise from your choice of the zero of energy?

(c) Show explicitly any effects of this divergence on calculations of the

(d) Is the divergence affected if the single atom is assumed to be confined to a box of finite volume L^3 in order to do a quantum calculation of the full partition function? Explain your answer.

(UC, Berkeley)

average thermal energy U .

Solution:

degeneracy $2n^2$, where $n = 1, 2, 3, \dots$. Therefore

(a) The internal energy levels of hydrogen are given by $-E_0/n^2$ with

$$Z = \sum_{n=1}^{\infty} 2n^2 \exp(-E_0/n^2/kT)$$

When $T = 0$, the expression has no meaning; when $T \neq 0$, it diverges.

(b) The divergence has nothing to do with the choice of the zero of energy. If we had chosen then

which would still diverge.

Statistical Physics

(c) When $T \neq 0$,

213

$n = 1$

That is to say, because of thermal excitation (no matter how low the temperature is, provided $T \neq 0$), the electrons cannot be bounded by the nuclei.

(d) The divergence has its origin in the large degeneracy of hydrogen's highly excited states. If we confine the hydrogen molecule in a box of volume L^3 , these highly excited states no longer exist and there will be no divergence.

2046

The average kinetic energy of the hydrogen atoms in a certain stellar

(a) What is the temperature of the atmosphere in Kelvins?

(b) What is the ratio of the number of atoms in the second excited

(c) Discuss qualitatively the number of ionized atoms. Is it likely to atmosphere (assumed to be in thermal equilibrium) is 1.0 eV .

state ($n = 3$) to the number in the ground state?

be much greater than or much less than the number in $n = 3$? Why?

Solution:

(wisco nsin)

(a) The temperature of the stellar atmosphere is

$$T = -Z E = 2 \times 1.6 \times 10^{-19} = 7.7 \times 10^3 \text{ K} . \quad 3k \quad 3 \times 1.38 \times$$

(b) The energy levels for hydrogen atom are

$$E_n = \left(-\frac{13.6}{n^2} \right) \text{ eV} .$$

Using the Boltzmann distribution, we get

214 Problem Solutions on Thermodynamics 6' Statistical Mechanics

Inserting $E_1 = -13.6$ eV, $E_3 = (-13.6/9)$ eV, and $kT = (2/3)$ eV into the above, we have $N_3/N_1 = 1.33 \times$

(c) The number of ionized atoms is the difference between the total number of atoms and the total number of atoms in bound states, i.e., the number of atoms in the level $n = \infty$. Obviously, it is much smaller than

the number in $n = 3$. Thus $N_{ion} = \exp \left(-\frac{E_3}{kT} \right) N_3$, i.e., N_{ion} is about one-tenth of N_3 .

N_3

2047

A monatomic gas consists of atoms with two internal energy levels: a ground state of degeneracy g_1 and a low-lying excited state of degeneracy g_2 at an energy E above the ground state. Find the specific heat of this gas.

(CUSPEA)

Solution:

According to the Boltzmann distribution, the average energy of the atoms is

where E_0 is the dissociation energy of the ground state (we choose the ground state as the zero point of energy). Thus

2048

Consider a system which has two orbital (single particle) states both of the same energy. When both orbitals are unoccupied, the energy of the system is zero; when one orbital or the other is occupied by one particle, the energy is ϵ . We suppose that the energy of the system is much higher, say infinitely high, when both orbitals are occupied. Show that the ensemble average number of particles in the level is

Statistical Physics 215

energy is ϵ . We suppose that the energy of the system is much higher, say infinitely high, when both orbitals are occupied. Show that the ensemble average number of particles in the level is

(UC, Berkeley)

The probability that a microscopic state is occupied is proportional to

Solution:

its Gibbs factor $\exp[-\beta \epsilon]$. We thus have

(a) State the Maxwell-Boltzmann energy distribution law.

(b) Assume the earth's atmosphere is pure nitrogen in thermodynamic equilibrium at a temperature of 300 K. Calculate the height above sea-level at which the density of the atmosphere is one half its sea-level value.

Solution:

(a) The Maxwell-Boltzmann energy distribution law: For a system of gas in equilibrium, the number of particles whose coordinates are between

r and $r + dr$ and whose velocities are between v and $v + dv$ is

Define

terms. Discuss briefly an application where the law fails.

(wisco nsin)

$$dN = n_0 \left(\frac{L}{\lambda}\right)^3 e^{-\epsilon/kT} dv$$

where n_0 denotes the number of particles in a unit volume for which the

potential energy ϵ is zero, $\epsilon = \epsilon_0 + \epsilon_1$ is the total energy, $dv = du, du = du_x, du_y, du_z$,
 $dr = dx dy dz$.

It is valid for localized

systems, classical systems and non-degenerate quantum systems. It does not hold for degenerate non-localized quantum systems, e.g., a system of electrons of spin $1/2$ at a low temperature and of high density.

The MB distribution is a very general law.

(b) We choose the z -axis perpendicular to the sea level and $z = 0$ at the sea level. According to the MB distribution law, the number of molecules in volume element $dx dy dz$ at height z is $dN = n_0 e^{-mgz/kT} dx dy dz$. Then the number of molecules per unit volume at height z is

Thus

$$kT \ln n = RT \ln n_0$$

$$n = n_0 e^{-mgz/kT}$$

$$z = -\frac{kT}{mg} \ln \frac{n}{n_0}$$

The molecular weight of the nitrogen gas is $M = 28 \text{ g/mol}$. With $g = 9.8 \text{ m/s}^2$, $R = 8.31 \text{ J/K.mole}$, $T = 300 \text{ K}$, we find $z = 6297 \text{ m}$ for $n/n_0 = 1/2$. That is, the density of the atmosphere at the height 6297m is one-half the sea level value.

2050

A circular cylinder of height L , cross-sectional area A , is filled with a gas of classical point particles whose mutual interactions can be ignored. The particles, all of mass m , are acted on by gravity (let g denote the gravitational acceleration, assumed constant). The system is maintained in thermal equilibrium at temperature T . Let c_v be the constant volume specific heat (per particle). Compute c_v as a function of T , the other parameters given, and universal parameters. Also, note especially the result for the limiting cases, $T \rightarrow 0$, $T \rightarrow \infty$.

(CUSPEA)

Solution:

of the molecules is

Let z denote the height of a molecule of the gas. The average energy

$$e = \frac{3}{2} kT + mgz,$$

where z is the average height. According to the Boltzmann distribution, the probability density that the molecule is at height z is $p(z) = \frac{1}{L} e^{-mgz/kT}$. Hence

$$\langle z \rangle = \int_0^L z p(z) dz = \frac{kT}{mg}$$

Statistical Physics 217

and

$$\langle z^2 \rangle = \frac{2kT}{mg}$$

$$e = \frac{3}{2} kT + \frac{kT}{mg} \left(\frac{mg}{kT} \right)^2 = \frac{5}{2} kT$$

$$c_v = \frac{5}{2} k$$

$$c_v = \frac{5}{2} k \quad (T \rightarrow 0)$$

$$c_v = \frac{3}{2} k \quad (T \rightarrow \infty)$$

$$c_v = \frac{5}{2} k, \text{ for } T \rightarrow 0,$$

$$c_v = \frac{3}{2} k, \text{ for } T \rightarrow \infty.$$

Fig. 2.12

2051

Ideal monatomic gas is enclosed in cylinder of radius a and length L . The cylinder rotates with angular velocity ω about its symmetry axis and the ideal gas is in equilibrium at temperature T in the coordinate system rotating with the cylinder. Assume that the gas atoms have mass m , have no internal degrees of freedom, and obey classical statistics.

- (a) What is the Hamiltonian in the rotating coordinates system?
- (b) What is the partition function for the system?
- (c) What is the average particle number density as a function of r ?

(MIT)

Solution:

(a) The Hamiltonian for a single atom is

$$h' = \frac{p^2}{2m} - m\omega^2 r^2/2,$$

$2m$

L

$0 \leq r \leq a, (z \in [-L/2, L/2])$,

m , otherwise.

$4(\omega, z) =$

218 Problem 8 & Solutions on Thermodynamics & Statistical Mechanics

The Hamiltonian for the system is

(b) The partition function is

(c) The average particle number density is

$$N/V = N \int d^3p' \exp[-\beta(\frac{p'^2}{2m} + \frac{1}{2} m\omega^2 r^2)]/z$$

2052

Find the particle density as a function of radial position for a gas of N molecules, each of mass M , contained in a centrifuge of radius R and length L rotating with angular velocity ω about its axis. Neglect the effect of gravity and assume that the centrifuge has been rotating long enough for the gas particles to reach equilibrium.

(Chicago)

Fig. 2.13.

Statistical Physics 219

Solution:

r . But in the rotational system S' , the energy of a particle is

In the rest system S , the energy E is independent of the radial distance

1 1

2 2

$$E(r) = \frac{1}{2} M \omega^2 r^2$$

The effect of rotation is the same as that of an additional external field acting on the system of

1

2

$$U(r, J) = - \frac{1}{2} M \omega^2 r^2$$

Using the Boltzmann distribution we get the particle number density

$$n(r) = A \exp(-\beta g) = A \exp(-\beta M_w 2r^2 / 2 \mathcal{I})$$

where the normalization factor A can be determined by $\int n(r) dV = N$,
Thus we have

$$M_w 2r^2$$

$$N M_w 2 (k T) \quad n(r) = 2.1 r k T L$$

2053

Suppose that a quantity of neutral hydrogen gas is heated to a temperature T . T is sufficiently high that the hydrogen is completely ionized, but low enough that $kT/m_e c^2 \ll 1$ (m_e is the mass of the electron). In this gas, there will be a small density of positrons due to processes such

as $e^- + e^- \rightarrow e^- + e^- + e^- + e^+$ or $e^- + p^+ \rightarrow e^- + p^+ + e^- + e^+$ in which electron-positron pairs are created and destroyed.

For this problem, you need not understand these reactions in detail.

Just assume that they are reactions that change the number of electrons and positrons, but in such a way that charge is always conserved.

220 Problem 8 d Solution 8 on Thermodynamics d Statistical Mechanics 8

Suppose that the number density of protons is $10^{11}/\text{cm}^3$. Find the chemical potentials for the electrons and positrons. Find the temperature at which the positron density is $1/\text{cm}^3$. Find the temperature at which it is $10^{10}/\text{cm}^3$.

(Prince **ton**)

Solution:

For $kT/m_e c^2 \ll 1$, nuclear reactions may be neglected. From charge

conservation, we have $n^- = n_p^+ + n^+$, where n^- , n^+ are the number densities of electrons and positrons respectively. For a non-relativistic nondegenerate case, we have

$$n^- = 2 \left(\frac{2 \pi m_e k T}{h^2} \right)^{3/2} \exp(\beta \mu^-),$$

where μ^- and μ^+ are the chemical potentials of electrons and positrons respectively. From the chemical equilibrium condition, we obtain $\mu^- = -\mu^+ = \mu$. Hence

$$n^+/n^- = \exp(-2\mu/kT).$$

For $n^+ = 1/\text{cm}^3$, $n^- = n_p = 10^{11}/\text{cm}^3$, we have $\exp(\mu/kT) = 10^5$ or $\mu/kT = 11.5$. Substituting these results into the expression of n^- , we have

$T = 1.2 \sim 1 \text{ K}$, $\mu = 1.6 \times 10^{-7} \text{ erg}$. For $n^+ = 10^{10}/\text{cm}^3$, $\exp(\mu/kT) = 10^4$, $\mu/kT = 9.2$. Substituting these results into the expression of n^+ , we get

$T = 1.5 \times 10^8 \text{ K}$, $\mu = 8.4 \times 10^{-7} \text{ erg}$.

2054

Consider a rigid lattice of distinguishable spin $1/2$ atoms in a magnetic field. The spins have two states, with energies $-p\omega$ and $+p\omega$ for spins up (1) and down (2), respectively, relative to \mathbf{H} . The system is at temperature T .

(a) Determine the canonical partition function Z for this system.

(b) Determine the total magnetic moment $M = p\omega(N_+ - N_-)$ of the

(c) Determine the entropy of the system.

(wisconsin)

Solution:

(a) The partition function is

$$Z = \exp(x) + \exp(-x),$$

where $x = \mu g H / kT$.

(b) The total magnetic moment is

a

$$aH$$

$$M = \mu g (N_+ - N_-) = NkT \ln Z$$

$$= N \mu g \tanh(x).$$

(c) The entropy of the system is

$$S = Nk(\ln Z - \beta \mu g \tanh(x))$$

$$= Nk(\ln 2 + \ln(\cosh x)) - x \tanh(x).$$

2055

A paramagnetic system consists of N magnetic dipoles. Each dipole carries a magnetic moment μ which can be treated classically. If the system at a finite temperature T is in a uniform magnetic field H , find

(a) the induced magnetization in the system, and

(b) the heat capacity at constant H .

(UC, Berkeley)

Solution:

(a) The mean magnetic moment for a dipole is

$$\int \mu \cos \theta \exp(x \cos \theta) d\Omega \int \exp(x \cos \theta) d\Omega$$

$$\mu \int \cos \theta \exp(x \cos \theta) \sin \theta d\theta \int_0^{2\pi} d\phi \int_0^\pi \exp(x \cos \theta) \sin \theta d\theta$$

$$= \mu \int_{-1}^1 x \exp(xz) dz$$

$$= \mu [\exp(xz)]_{-1}^1$$

$$= \mu c [\exp(x) - \exp(-x)]$$

where $x = \mu H / kT$. Then the induced magnetization in the system is

$$\langle M \rangle = N \langle \mu \rangle = N \mu \tanh(x)$$

222 Problems of Solutions on Thermodynamics and Statistical Mechanics

$$a(u) = -kT \ln(1 - z^2 \text{csch}^2 z)$$

$$aT(b) = -kT \ln(1 - z^2 \text{csch}^2 z)$$

2056

Consider a gas of spin $1/2$ atoms with density n atoms per unit volume.

Each atom has intrinsic magnetic moment μ and the interaction between atoms is negligible.

Assume that the system obeys classical statistics.

(a) What is the probability of finding an atom with μ parallel to the applied magnetic field H at absolute temperature T ? With μ anti-parallel to H ?

(b) Find the mean magnetization of the gas in both the high and low

(c) Determine the magnetic susceptibility χ in terms of μ .

temperature limits?

(SUNY, Buffalo)

Solution:

(a) The interaction energy between an atom and the external magnetic field is $E = -\mu \cdot H$. By classical Boltzmann distribution, the number of atoms per unit volume in the solid angle element $d\Omega$ in the direction (θ, ϕ) ,

is

$g \exp(-PE) d\Omega = g \exp(\mu H \cos\theta / kT) d\Omega$,
 where θ is the angle between μ and \mathbf{H} and g is the normalization factor
 given by
 i.e.,

$$g \int \exp(\mu H \cos\theta / kT) \sin\theta d\theta d\phi = 1,$$

$$\int_0^\pi \int_0^{2\pi} \exp(\mu H \cos\theta / kT) \sin\theta d\theta d\phi = 1$$

$$2\pi g \int_0^\pi \exp(\mu H \cos\theta / kT) \sin\theta d\theta = 1$$

Hence the probability density for the magnetic moment of an atom to be parallel to \mathbf{H} is

and that for the magnetic moment to be antiparallel to \mathbf{H} is

Statistical Physics 223

(b) The average magnetization of the gas at temperature T is
 At high temperatures, $\mu H \ll kT$. Let $\mu H = x$, and expand kT

$$\frac{x}{kT} \ll 1$$

At low temperatures, $x \gg 1$, then

$$\coth x \approx 1 + \frac{1}{2x^2}$$

and $\mathcal{M} \approx \mu n$.

(c) The magnetic susceptibility of the system is

$$\chi = \frac{\mathcal{M}}{H} \approx \frac{\mu n}{H} \approx \frac{\mu^2 n}{kT}$$

at low temperature .

There is spontaneous magnetization in the limit of low temperatures.

2057

A material consists of n independent particles and is in a weak external magnetic field H . Each particle can have a magnetic moment μ along

the magnetic field, where $m = J, J-1, \dots, -J+1, -J$, J being an integer,

and μ is a constant. The system is at temperature T .

(a) Find the partition function for this system.

(b) Calculate the average magnetization, \mathcal{M} , of the material.

(c) For large values of T find an asymptotic expression for \mathcal{M} .

(MIT)

224 Problem 3 d Solution on *thermodynamic^ d Statistical Mechanics*

Solution:

(a) The partition function is

$$Z = \sum_{m=-J}^J \exp(\mu H m / kT) = \sinh \left(\frac{\mu H}{kT} \right)$$

(b) The average magnetization is

$$\mathcal{M} = - \left(\frac{\partial}{\partial H} \right) T = N k T \left(\frac{\partial \ln Z}{\partial H} \right)$$

$$= 2 \mu \left[(2J+1) \coth \left(\frac{\mu H}{kT} \right) - \coth \left(\frac{\mu H}{kT} \right) \right]$$

$$2 \left[\frac{2kT}{2kT} \right]$$

(c) When $kT \gg p H$, using $\cos x \approx 1 - \frac{x^2}{2}$, for $x < 1$ we get

$$M w - 1 N J (J + 1) - P 2 H$$

3 kT

2058

Two dipoles, with dipole moments M_1 and M_2 , are held apart at a separation R , only the orientations of the moments being free. They are in thermal equilibrium with the environment at temperature T . Compute the mean force F between the dipoles for the high temperature limit $\frac{p}{kT} \ll 1$. The system is to be treated classically.

Remark: The potential energy between two dipoles is:

$$U = \frac{1}{4\pi\epsilon_0 R^3} (3(\mathbf{M}_1 \cdot \mathbf{R})(\mathbf{M}_2 \cdot \mathbf{R}) - (\mathbf{M}_1 \cdot \mathbf{M}_2)R^2)$$

$$U = \frac{1}{4\pi\epsilon_0 R^3} (3M_1 M_2 \cos\theta_1 \cos\theta_2 - M_1 M_2 \cos\phi)$$

$$U = \frac{1}{4\pi\epsilon_0 R^3} (3M_1 M_2 \cos\theta_1 \cos\theta_2 - M_1 M_2 \cos\phi)$$

(Princeton)

Solution:

Taking the z-axis along the line connecting M_1 and M_2 , we have

$$U = \frac{1}{4\pi\epsilon_0 R^3} [2 \cos\theta_1 \cos\theta_2 - \sin\theta_1 \sin\theta_2 \cos(\phi_1 - \phi_2)]$$

R3

Statistical Physics 225

The classical partition function is

$$Z = \int \int \int \int \exp(-\beta U) d\theta_1 d\theta_2 d\phi_1 d\phi_2$$

As $\beta U \ll 1$, expanding the integrand with respect to βU , retaining only the first non-zero terms, and noting that the integral of a linear term of $\cos\phi$ is zero, we have

$$Z \approx \int \int \int \int (1 - \beta U) d\theta_1 d\theta_2 d\phi_1 d\phi_2$$

$$Z = \int \int \int \int \left[1 - \beta \frac{1}{4\pi\epsilon_0 R^3} (3M_1 M_2 \cos\theta_1 \cos\theta_2 - M_1 M_2 \cos\phi) \right] d\theta_1 d\theta_2 d\phi_1 d\phi_2$$

$$Z = \int \int \int \int 1 d\theta_1 d\theta_2 d\phi_1 d\phi_2 - \beta \frac{1}{4\pi\epsilon_0 R^3} (3M_1 M_2 \int \int \int \int \cos\theta_1 \cos\theta_2 d\theta_1 d\theta_2 - M_1 M_2 \int \int \int \int \cos\phi d\phi_1 d\phi_2)$$

$$Z = \int \int \int \int 1 d\theta_1 d\theta_2 d\phi_1 d\phi_2 - \beta \frac{1}{4\pi\epsilon_0 R^3} (3M_1 M_2 \int \int \int \int \cos\theta_1 \cos\theta_2 d\theta_1 d\theta_2 - M_1 M_2 \int \int \int \int \cos\phi d\phi_1 d\phi_2)$$

$$Z = \int \int \int \int 1 d\theta_1 d\theta_2 d\phi_1 d\phi_2 - \beta \frac{1}{4\pi\epsilon_0 R^3} (3M_1 M_2 \int \int \int \int \cos\theta_1 \cos\theta_2 d\theta_1 d\theta_2 - M_1 M_2 \int \int \int \int \cos\phi d\phi_1 d\phi_2)$$

2059

The molecule of a perfect gas consists of two atoms, of mass m , rigidly separated by a distance d . The atoms of each molecule carry charges q and $-q$ respectively, and the gas is placed in an electric field E . Find the mean polarization, and the specific heat per molecule, if quantum effects can be neglected.

State the condition for this last assumption to be true.

(UC, Berkeley)

Solution:

field is E . The energy of a dipole in the field is

Assume that the angle between a molecular dipole and the external

226

Then

Problems and Solutions on Thermodynamics and Statistical Mechanics

The condition for classical approximation to be valid is that the quantization

tion of the rotational energy can be neglected, that is, $kT \gg -$
 md^2 .

2060

The response of polar substances (e.g., HCl, H₂O, etc) to applied electric fields can be described in terms of a classical model which attributes to each molecule a permanent electric dipole moment of magnitude p .

(a) Write down a general expression for the average macroscopic polarization j (dipole moment per unit volume) for a dilute system of n molecules per unit volume at temperature T in a uniform electric field E .

(b) Calculate explicitly an approximate result for the average macroscopic polarization j at high temperatures ($kT > pE$).

(MIT)

Statistical Physics 227

Solution:

(a) The energy of a dipole in electric field is

$$U = -\mathbf{p} \cdot \mathbf{E} = -pE \cos \theta$$

The partition function is then

The polarization is

$$P = \frac{1}{N} \frac{\partial \ln Z}{\partial E}$$

(b) Under the condition $z = - \ll 1$, $\coth z \approx \frac{1}{z}$, and we have

$$j = np \frac{2E}{3kT}$$

2061

The entropy of an ideal paramagnet in a magnetic field is given approximately

$$S = S_0 - \frac{U^2}{2C}$$

where U is the energy of the spin system and C is a constant with fixed mechanical parameters of the system.

(a) Using the fundamental definition of the temperature, determine

(b) Sketch a graph of U versus T for all values of T ($-\infty < T < \infty$).

(c) Briefly tell what physical sense you can make of the negative temperature U of the spin system as a function of T .

perature part of your result.

Solution:

(a) From the definition of temperature,

$$\frac{1}{T} = - \left(\frac{\partial S}{\partial U} \right)_C$$

we have $U = -$

$$2CT^2$$

228 Problems in Statistical Mechanics

(b) We assume $C > 0$. The change of U with T is shown in the

Fig. 2.14.

Fig. 2.14.

(c) Under normal conditions, the number of particles in higher energy states is smaller than that in lower energy states. The physical significance of a negative temperature is that under such condition the number of particles in an excited state is greater than that in the ground state. That is, there are more particles with magnetic moments anti-parallel to the magnetic field than those with magnetic moments parallel to the magnetic field.

2062

Consider a system of N non-interacting particles ($N \gg 1$) in which the energy of each particle can assume two and only two distinct values, 0 and E ($E > 0$). Denote by n_0 and n_1 the occupation numbers of the energy levels 0 and E , respectively. The fixed total energy of the system is U .

- (a) Find the entropy of the system.
 (b) Find the temperature as a function of U . For what range of values
 (c) In which direction does heat flow when a system of negative temperature is brought into thermal contact with a system of positive temperature?

Why?

(Princeton)

Solution:

of no is $T < 0$?

(a) The number of states is

Statistical Physics 229

$N!$

Hence $S = k \ln N = k \ln n!$

$n!$

(b) $n! / n^0 = \exp(-E/kT)$, where we have assumed the energy levels to be nondegenerate. Thus

When $n_0 < N/2$, we get $T < 0$.

(c) Heat will flow from a negative temperature system to a positive temperature system. This is because the negative temperature system has higher energy on account of population inversion, i.e., it has more particles in higher energy states than in lower energy states.

3. BOSE-EINSTEIN AND FERMI-DIRAC STATISTICS

(2063-2 115)

2063

A system of N identical spinless bosons of mass m is in a box of volume $V = L^3$ at temperature $T > 0$.

(a) Write a general expression for the number of particles, $n(E)$, having an energy between E and $E + dE$ in terms of their mass, the energy, the temperature, the chemical potential, the volume, and any other relevant quantities.

(b) Show that in the limit that the average distance, d , between the particles is very large compared to their de Broglie wavelength (i.e., $d \gg \lambda$)

A the distribution becomes equal to that calculated using the classical (Boltzmann) distribution function.

(c) Calculate the 1st order difference in average energy between a system of N non-identical spinless particles and a system of N identical spinless bosons when $d \gg \lambda$. For both systems the cubical box has volume $V = L^3$ and the particles have mass m .

(UC, Berkeley)

230 Problems 8 *Soldano on Thermodynamics* *FY Statistical Mechanics*

Solution:

(a) The number of particles is

(b) In the approximation of a dilute gas, we have $\exp(-p/kT) \gg 1$, and the Bose-Einstein distribution becomes the Boltzmann distribution.

We will prove as follows that this limiting condition is just $d \gg \lambda$.

Since

we have

where $\lambda = h / \sqrt{2mE}$ is the de Broglie wavelength of the particle's thermal

motion, and $d = V/N$.

Thus the approximation $\exp(-p/kT) \gg 1$ is equivalent to $d \gg \lambda$.

(c) In the 1st order approximation

the average energy is

Statistical Physics 231

2064

Consider a quantum-mechanical gas of non-interacting spin *zero* bosons, each of mass m which are free to move within volume V .

(a) Find the energy and heat capacity in the very low temperature region. Discuss why it is appropriate at low temperatures to put the chemical potential equal to zero.

Prove that the energy is proportional to T^4 .

Note: Put all integrals in dimensionless form, but do not evaluate.

Solution:

(b) Show how the calculation is modified for a photon (mass = 0) gas.

(UC, Berkeley)

(a) The Bose distribution

requires that $\mu \leq 0$. Generally

When T decreases, the chemical potential μ increases until $\mu = 0$, for which Bose condensation occurs when the temperature continues to decrease with $\mu = 0$. Therefore, in the limit of very low temperatures, the Bose system can be regarded as having $\mu = 0$. The number of particles at the noncondensed state is not conserved. The energy density u and specific heat c are thus obtained as follows:

(b) For a photon gas, we have $\mu = 0$ at any temperature and $\epsilon = \hbar\omega$.

$\omega^2 d\omega$

The density of states is - and the energy density is

$$u = -\int_0^\infty \frac{1}{\beta} \ln(1 - e^{-\beta \hbar\omega}) \omega^3 d\omega = \frac{15}{16\pi^2} \frac{(kT)^4}{(\hbar c)^3} \int_0^\infty \frac{x^3 dx}{e^x - 1}$$

$$c = \frac{15}{4\pi^2} \frac{(kT)^3}{(\hbar c)^3} \int_0^\infty \frac{x^3 dx}{e^x - 1}$$

232 Problems in Statistical Mechanics

2065

A gas of N spinless Bose particles of mass m is enclosed in a volume V at a temperature T .

(a) Find an expression for the density of single-particle states $D(\epsilon)$ as a function of the single-particle energy ϵ . Sketch the result.

(b) Write down an expression for the mean occupation number of a single particle state, \bar{n} , as a function of ϵ , T , and the chemical potential $\mu(T)$. Draw this function on your sketch in part (a) for a moderately high temperature [that is, a temperature above the Bose-Einstein transition. Indicate the place on the ϵ -axis where $\epsilon = \mu$].

(c) Write down an integral expression which implicitly determines $\mu(T)$. Referring to your sketch in (a), determine in which direction $\mu(T)$ moves as T is lowered.

(d) Find an expression for the Bose-Einstein transition temperature, T_c , below which one must have a macroscopic occupation of some singleparticle states. Leave your answer in terms of a dimensionless integral.

(e) What is \bar{n} for $T < T_c$?

Describe $\bar{n}(\epsilon)$ for $T < T_c$?

(f) Find an exact expression for the total energy, $U(T, V)$ of the gas for $T < T_c$. Leave your answer in terms of a dimensionless integral.

(MIT)

Solution:

(a) From $e = \mathbf{p}^2/2m$ and

$$d^3r = 4\pi p^2 dp$$

$$D(\epsilon)d\epsilon = \frac{4\pi}{h^3} m^{3/2} \sqrt{\epsilon} d\epsilon$$

we find

$$D(\epsilon) = \frac{2\sqrt{2}}{\pi^2} \left(\frac{m}{h^2}\right)^{3/2} \sqrt{\epsilon}$$

$$h^3 D(\epsilon) = \frac{2\sqrt{2}}{\pi^2} m^{3/2} \sqrt{\epsilon}$$

Statistical Physics 233

The result is shown in Fig. 2.15

(c) With $\mu = -$ we have $N =$

$$\frac{2m}{h^3}$$

or

$$\frac{2m}{h^3}$$

$$\frac{2m}{h^3} \exp(-\mu/kT)$$

$$\frac{2m}{h^3}$$

$$\frac{h^3}{2m}$$

$$N/V = (2mkT)^{3/2}$$

where $\mu = p/kT \rightarrow 0$. As N/V remains unchanged when T decreases,

$p(T)$ increases and approaches zero.

(d) Let n be the number density and T_c , the critical temperature. Note that at temperature T_c , the chemical potential μ is near to zero and the particle number of the ground state is still near to zero, so that we have

$$= -2(T_c mkT_c)^{3/2}$$

$$\frac{h^3}{2m}$$

where the integral

$$= 1.3066$$

Hence

$$T_c =$$

(e) For bosons, $\mu < 0$. When $T \rightarrow T_c$, $\mu \rightarrow 0$ and we have

$$n_{>0} = \exp(\mu/kT) \rightarrow 1$$

$$\frac{234}{h^3}$$

and

2067

Consider a gas of non-interacting, non-relativistic, identical bosons.

Explain whether and why the Bose-Einstein condensation effect that applies to a three-dimensional gas applies also to a two-dimensional gas and to a one-dimensional gas.

(Princeton)

Solution:

Briefly speaking, the Bose-Einstein condensation occurs when $p = 0$.

For a two-dimensional gas, we have

If $p = 0$, the above expression diverges. Hence $p \neq 0$ and Bose-Einstein condensation does not occur.

For a one-dimensional gas, we have

If $p = 0$, the integral diverges. Again, Bose-Einstein condensation does not occur.

2068

Consider a photon gas enclosed in a volume V and in equilibrium at temperature T . The photon is a massless particle, so that $E = pc$.

(a) What is the chemical potential of the gas? Explain.

(b) Determine how the number of photons in the volume depends upon the temperature.

(c) One may write the energy density in the form

Statistical Physics 237

Determine the form of $\rho(\omega)$, the spectral density of the energy.

(d) What is the temperature dependence of the energy E ?

(UC, Berkeley)

Solution :

(a) The chemical potential of the photon gas is zero. Since the number of photons is not conserved at a given temperature and volume, the average

photon number is determined by the expression $\left(\frac{\partial \ln Z}{\partial N} \right)_{T, V} = 0$, then

(b) The density of states is $8\pi V p^2 dp / h^3$, or $V \omega^2 d\omega / \pi^2 c^3$. Then the number of photons is

Hence

and $E \propto T^4$

2069

(a) Show that for a photon gas $p = U/3V$.

(b) Using thermodynamic arguments (First and Second Laws), and

the above relationship between pressure and energy density, obtain the dependence of the energy density on the temperature in a photon gas.

(UC, Berkeley)

238 Problems and Solutions on Thermodynamics and Statistical Mechanics

Solution:

(a) The density of states is

$$D(\epsilon) d\epsilon = a V \epsilon^2 d\epsilon,$$

where a is a constant.

With

$$\ln E = - \int D(\epsilon) \ln(1 - e^{-\beta \epsilon}) d\epsilon,$$

we have

$$U$$

$$3V$$

$$dE = -$$

(b) For thermal radiation, we have

$$U(T, V) = u(T) V.$$

Using the following formula of thermodynamics

$$T du =$$

$$3dT$$

we get $u = \frac{3}{4} T^4$, i.e. $u = \frac{3}{4} T^4$, where $\frac{3}{4}$ is a constant.

2070

Consider a cubical box of side L with no matter in its interior. The walls are fixed at absolute temperature T , and they are in thermal equilibrium with the electromagnetic radiation field in the interior.

(a) Find the mean electromagnetic energy per unit volume in the frequency

range from ω to $\omega + d\omega$ as a function of ω and T . (If you wish to start with a known distribution function - e.g., Maxwell-Boltzmann, Planck, etc. - you need not derive that function.)

(b) Find the temperature dependence of the total electromagnetic energy per unit volume. (Hint: you do not have to actually carry out the integration of the result of part (a) to answer this question.)

(SVNY, Buflulo)

Statistical Physics 239

Solution:

$p + dp$ is given by

(a) The mean electromagnetic energy in the momentum interval p to

$$V \frac{d^3 p}{(2\pi\hbar)^3} e^{-\beta h \omega} = 2 \cdot \frac{V}{(2\pi\hbar)^3} e^{-\beta h \omega} \omega^2 d\omega$$

where the factor 2 corresponds to the two polarizations of electromagnetic waves and $V = L^3$.

Making use of $p = \hbar\omega/c$, we obtain the mean electromagnetic energy

in the frequency interval ω to $\omega + d\omega$:

$$V \frac{d^3 p}{(2\pi\hbar)^3} e^{-\beta h \omega} \omega^2 d\omega$$

$$dE = 2 \frac{V}{(2\pi\hbar)^3} e^{-\beta h \omega} \omega^2 d\omega$$

The corresponding energy density is

(b) The total electromagnetic energy per unit volume is

$$u = \int_0^\infty \frac{dE}{V} = \frac{2}{(2\pi\hbar)^3} \int_0^\infty e^{-\beta h \omega} \omega^3 d\omega = \frac{2}{(2\pi\hbar)^3} \frac{3!}{\beta^4} \int_0^\infty e^{-x} x^3 dx = \frac{6}{\pi^2} \frac{1}{\beta^4} = \frac{6}{\pi^2} \left(\frac{kT}{\hbar c}\right)^4$$

Thus $u \propto T^4$.

2071

A historic failure of classical physics is its description of the electromagnetic radiation from a black body. Consider a simple model for an ideal black body consisting of a cubic cavity of side L with a small hole in one side.

(a) Assuming the classical equipartition of energy, derive an expression for the average energy per unit volume and unit frequency range (Rayleigh-Jeans' Law). In what way does this result deviate from actual observation?

Fig. 2.16.

240 Problems in Statistical Mechanics

(b) Repeat the calculation, now using quantum ideas, to obtain an expression that properly accounts for the observed spectral distribution (Planck's Law).

(c) Find the temperature dependence of the total power emitted from (CUSPEA)

Solution:

(a) For a set of three positive integers (n_x, n_y, n_z) , the electromagnetic field at thermal equilibrium in the cavity has two modes of oscillation with

the frequency $\omega(n_x, n_y, n_z) = \pi c \sqrt{n_x^2 + n_y^2 + n_z^2} / L$. Therefore, the number of modes within the frequency interval ω to $\omega + d\omega$ is

$$dN = \frac{4\pi \omega^2 L^3}{c^3} d\omega$$

Equipartition of energy then gives an energy density

$$dU = \frac{1}{2} dN kT$$

$$dU = \frac{1}{2} \frac{4\pi \omega^2 L^3}{c^3} d\omega kT$$

$$dU = \frac{2\pi \omega^2 L^3}{c^3} d\omega kT$$

$$U = \int_0^\infty \frac{2\pi \omega^2 L^3}{c^3} kT d\omega$$

$$= \frac{8\pi^2 kT}{15 c^3} \omega^3$$

When ω is very large, this expression does not agree with experimental observations since it implies $U \propto \omega^3$.

(b) For oscillations of frequency ω , the average energy is

$$\frac{\sum_{n=0}^{\infty} n h \omega e^{-n h \omega / kT}}{\sum_{n=0}^{\infty} e^{-n h \omega / kT}}$$

which is to replace the classical quantity kT to give

$$\frac{h \omega}{e^{h \omega / kT} - 1}$$

(c) The energy radiated from the hole per unit time is

$$P = \int_0^\infty \frac{dU}{dt} d\omega$$

$$= \int_0^\infty \frac{2\pi \omega^2 L^3}{c^3} \frac{h \omega}{e^{h \omega / kT} - 1} d\omega$$

2072

Electromagnetic radiation following the Planck distribution fills a cavity of volume V . Initially ω_m is the frequency of the maximum of the curve of $u(\omega)$, the energy density per unit angular frequency versus ω . If the volume is expanded quasistatically to $2V$, what is the final peak frequency ω_f of the $u(\omega)$ distribution curve? The expansion is adiabatic.

(UC, Berkeley)

Solution:

As the Planck distribution is given by $1/[\exp(h\omega/kT) - 1]$ and the density of states of a photon gas is

$$D(\omega)d\omega = \frac{\omega^2 d\omega}{\pi^2 c^3} (u = \text{const}),$$

the angular frequency ω which makes $u(\omega)$ extremum is $\omega = \gamma T$, where γ is a constant. On the other hand, from $dU = TdS - pdV$ and $U = 3pV$, we obtain $V^4 p^3 = \text{const}$ when $dS = 0$. Since $p \propto T^4$, we have

$$VT^3 = \text{const.},$$

2073

A He-Ne laser generates a quasi-monochromatic beam at 632863. The beam has an output power of 1 mW, a divergence angle of 0.01 rad, and a spectral linewidth of 0.01 nm. If a black body with an area of 1 cm² were used to generate such a beam after proper filtering, what should its temperature be approximately?

(UC, Berkeley)

watts), a divergence angle of

242 Problems in Statistical Mechanics

Solution:

of photons in the interval $d\lambda$:

Considering black body radiation in a cavity we get the number density n . The number of photons in the laser beam flowing through an area A per unit time is $dn' = cAdn$, and the output power is $W = E dn'$.

Introducing $E = hc/\lambda$ and $dn = n(\lambda)d\lambda$ into the expression, we obtain where

Therefore

$$W = \int A hc n(\lambda) d\lambda$$

$$W =$$

$$T = \frac{hc}{k \ln(2)}$$

$$k \ln(2)$$

Using the known quantities, we get

$$W = 3.60 \times 10^{-1} \text{ W}, T = 6 \times 10^9 \text{ K}.$$

2074

(a) Show that the number of photons in equilibrium at temperature T in a cavity of volume V is $N = V (kT/hc)^3 \times \text{constant}$.

(b) Use this result to obtain a qualitative expression for the heat capacity of a photon gas at constant volume.

(UC, Berkeley)

Solution:

(a) The density of states of the photon gas is given by

Statistical Physics 243

Thus

where

(b) The energy density is

therefore $C_v \propto T^3$.

2075

As you know, the universe is pervaded by 3K black body radiation. In a simple view, this radiation arose from the adiabatic expansion of a much hotter photon cloud which was produced during the big bang.

(a) Why is the recent expansion adiabatic rather than, for example,

(b) If in the next 10¹¹ years the volume of the universe increases by a factor of two, what then will be the temperature of the black body radiation? (Show your work.)

(c) Write down an integral which determines how much energy per cubic meter is contained in this cloud of radiation. Estimate the result within an order of magnitude in joules per (meter)³.

(Chicago)

Solution:

(a) The photon cloud is an isolated system, so its expansion is adiabatic. Is it isothermal?

(b) The energy density of black body radiation is $u = aT^4$, so that the

244 Problems in Statistical Mechanics

total energy $E \propto VT^4$. From the formula $TdS = dE + pdV$, we have

$$T \left(\frac{dE}{E} \right) = \left(\frac{dS}{S} \right) + \left(\frac{pdV}{E} \right) \sim$$

$\propto cVT^3$.

Hence $S = VT^3 \cdot \text{const.}$

For a reversible adiabatic expansion, the entropy S remains unchanged.

Thus when V doubles T will decrease by a factor **(2)^{-1/3}**. So after another

10¹¹ years, the temperature of black body radiation will become

$$T = 3\text{K}/2^{1/3}.$$

(c) The black body radiation obeys the Bose-Einstein Statistics:

where the factor **2** is the number of polarizations per state. Hence

2076

Our universe is filled with black body radiation (photons) at a temperature

$T = 3\text{ K}$. This is thought to be a relic, of early developments

following the 'big bang'.

(a) Express the photon number density n analytically in terms of T and universal constants. Your answer should explicitly show the dependence on T and on the universal constants. However, a certain numerical cofactor may be left in the form of a dimensionless integral which need not be evaluated at this stage.

(b) Now estimate the integral roughly, use your knowledge of the universal constants, and determine n roughly, to within about two orders of magnitude, for $T = 3\text{ K}$.

(C USPEA)

Solution:

(a) The Bose distribution is given by

$$n(\mathbf{k}) = 1/bP(P(\mathbf{k}) - 1)$$

Statistical Physics ~ 245

The total number of photons is then

where $E(k) = \hbar kc$ for photons and $\rho = \frac{2}{3}$. The factor **2** is due to the two directions of polarization. Thus

where

(b) When $T = 3\text{ K}$, $n \approx 1000/\text{cm}^3$.

2077

We are surrounded by black body photon radiation at **3K**. Consider the question of whether a similar bath of thermal neutrinos might exist.

(a) What kinds of laboratory experiments put the best limits on how

(b) The photon gas makes up **LOW** of the energy density needed to close the universe. Assuming the universe is no more than just closed, what order of magnitude limit does this consideration place on the neutrino's temperature?

hot a neutrino gas might be? How good are these limits?

(c) **In a** standard big-bang picture, what do you expect the neutrino temperature to be (roughly)?

(Princeton)

Solution:

(a) These are experiments to study the neutral weak current reaction

between neutrinos and electrons, $\nu_e + e^- \rightarrow \nu_e + e^-$, using neutrinos

created by accelerator at CERN. No such reactions were detected above the background and the confidence limit of measurements was

246 Problems & Solutions on Thermodynamics & Statistical Mechanics

90%. This gives an upper limit to the weak interaction cross section of

$\sigma < 2.6 \times 10^{-42} \text{E, cm}^2/\text{electron}$. With $E = kT$ we obtain $T < 10^4 \text{K}$.

(b) The energy density of the neutrino gas is $\rho_\nu = aT^4$, and that of the photon gas is $\rho_\gamma = aT^4$. As $\rho_\nu = 10^{-10} \rho_\gamma$, we have $T_\nu = T/10^{1.5}$. For $T = 3 \text{K}$, we get $T_\nu = 0.1 \text{K}$.

(c) At the early age of the universe (when $kT \ll mc^2$) neutrinos and other substances such as photons are in thermal equilibrium with $T = T_\nu = T_\gamma$, and both have energy distributions similar to that of black body radiation. Afterwards, the neutrino gas expands freely with the universe and its energy density has functional dependence $\rho_\nu \propto (v/R)^3$, where the frequency $\nu \propto 1/R$, the temperature $T \propto 1/R$, R being the "radius" of the universe. Hence the neutrino energies always follow the black body spectrum, just like the photons. However, because of the formation of photons by the annihilation of electron-positron pairs, $\rho_\gamma > \rho_\nu$, and the temperature of the photon gas is slightly higher than that of the neutrino gas. As the photon temperature at present is 3K , we expect $T_\nu < 3 \text{K}$.

2079

An n -dimensional universe.

In our three-dimensional universe, the following are well-known results from statistical mechanics and thermodynamics:

(a) The energy density of black body radiation depends on the temperature as T^a , where $a = 4$.

(b) In the Debye model of a solid, the specific heat at low temperatures

(c) The ratio of the specific heat at constant pressure to the specific

Derive the analogous results (i.e., what are a , b and γ) in the universe

depends on the temperature as T^a , where $a = 3$.

heat at constant volume for a monatomic ideal gas is $\gamma = 5/3$.

with n dimensions.

PIT)

Solution:

(a) The energy of black body radiation is

$E = \int_0^\infty \rho(\omega) d\omega$

$(2\pi\hbar)^{-3} \int_0^\infty \frac{c^3 \omega^3}{2\pi^2} \frac{1}{e^{\hbar\omega/kT} - 1} d\omega$

For the radiation we have $p = E/c$, so

where $x = \hbar\omega/kT$. Hence $\gamma = 4/3$.

(b) The Debye Model regards solid as an isotropic continuous medium with partition function

$$Z = \prod_{i=1}^{3N} \prod_{j=1}^{\infty} \left[1 - \exp\left(-\frac{\hbar \omega_j}{kT}\right) \right]^{-1}$$

$$Z(T, V) = \exp\left(-\frac{AEW}{2kT}\right) \prod_{i=1}^n \left[1 - \exp\left(-\frac{\hbar \omega_i}{kT}\right) \right]^{-1}$$

The Helmholtz free energy is

$$F = -kT \ln Z$$

$$F = -kT \ln \left[\exp\left(-\frac{AEW}{2kT}\right) \prod_{i=1}^n \left[1 - \exp\left(-\frac{\hbar \omega_i}{kT}\right) \right]^{-1} \right]$$

$$F = -kT \left[-\frac{AEW}{2kT} + \sum_{i=1}^n \ln \left[1 - \exp\left(-\frac{\hbar \omega_i}{kT}\right) \right] \right]$$

$$F = \frac{AEW}{2} - kT \sum_{i=1}^n \ln \left[1 - \exp\left(-\frac{\hbar \omega_i}{kT}\right) \right]$$

When N is very large,

$$F \approx \frac{AEW}{2} - kT \int_0^{\omega_D} g(\omega) \ln \left[1 - \exp\left(-\frac{\hbar \omega}{kT}\right) \right] d\omega$$

$$F \approx \frac{AEW}{2} - kT \int_0^{\omega_D} \frac{D(\omega)}{2\pi} \ln \left[1 - \exp\left(-\frac{\hbar \omega}{kT}\right) \right] d\omega$$

$$F \approx \frac{AEW}{2} - kT \int_0^{\omega_D} \frac{D(\omega)}{2\pi} \ln \left[1 - \exp\left(-\frac{\hbar \omega}{kT}\right) \right] d\omega$$

where ω_D is the Debye frequency. So we have

$$F \approx \frac{AEW}{2} - kT \int_0^{\omega_D} \frac{D(\omega)}{2\pi} \ln \left[1 - \exp\left(-\frac{\hbar \omega}{kT}\right) \right] d\omega$$

$$F \approx \frac{AEW}{2} - kT \int_0^{\omega_D} \frac{D(\omega)}{2\pi} \ln \left[1 - \exp\left(-\frac{\hbar \omega}{kT}\right) \right] d\omega$$

$$F \approx \frac{AEW}{2} - kT \int_0^{\omega_D} \frac{D(\omega)}{2\pi} \ln \left[1 - \exp\left(-\frac{\hbar \omega}{kT}\right) \right] d\omega$$

$$F \approx \frac{AEW}{2} - kT \int_0^{\omega_D} \frac{D(\omega)}{2\pi} \ln \left[1 - \exp\left(-\frac{\hbar \omega}{kT}\right) \right] d\omega$$

where $x_D = \hbar \omega_D / kT$. Hence

$$F \approx \frac{AEW}{2} - kT \int_0^{x_D} \frac{D(x)}{2\pi} \ln \left[1 - \exp\left(-\frac{x}{x_D}\right) \right] dx$$

$$F \approx \frac{AEW}{2} - kT \int_0^{x_D} \frac{D(x)}{2\pi} \ln \left[1 - \exp\left(-\frac{x}{x_D}\right) \right] dx$$

Statistical Physics 249

(c) The theorem of equipartition of energy gives the constant volume

$$c_v = \frac{1}{2} k$$

specific heat of a molecule as $c_v = \frac{1}{2} k$ where 1 is the number of degrees of freedom of the molecule. For a monatomic molecule in a space of n

dimensions, $1 = n$. With $c_p = c_v + k$, we get

$$c_p = \frac{3}{2} k$$

(a) Suppose one carries out a measurement of the specific heat at

constant volume, C_v , for some solid as a function of temperature, T and obtains the results:

T, C_v (arbitrary units)

Is the solid a conductor or an insulator? Explain.

(b) If the displacement of an atom about its equilibrium position in a harmonic solid is denoted by U , then the average displacement squared is given by

where M is the mass of the atom, $g(E)$ is a suitably normalized density of energy states and $n(E)$ is the Bose-Einstein occupation factor for phonons

of energy E . Assuming a Debye model for the density of states:

$$g(E) \sim E^2 / (A W^3) \sim$$

$$g(E) = 0$$

for $E < \hbar \omega_D$,

for $E > \hbar \omega_D$,

where ω_D is the Debye frequency, determine the temperature dependence of (U) for very high and very low temperatures. Do your results make sense?

(Chica g o)

250 Problems & Solutions on Thermodynamics & Statistical Mechanics

Solution:

constant at high temperatures. So it is an insulator.

(a) For the solid we have $C_v \propto T^3$ at low temperatures and $C_v =$

(b) The phonon is a boson. The Bose-Einstein occupation factor for

1

$$e^{E/kT} - 1$$

phonons of energy E is

$$n(E) =$$

so

$$\frac{1}{e^{E/kT} - 1} \sim \frac{1}{E/kT} \quad \text{for } E \gg kT$$

4M AWD M

If the temperature is high, i.e., $kT \gg E$,

If the temperature is low, i.e., $kT \ll E$.

These results show that the atoms are in motion at $T = 0$, and the higher the temperature the more intense is the motion.

2081

Graphite has a layered crystal structure in which the coupling between the carbon atoms in different layers is much weaker than that between the atoms in the same layer. Experimentally it is found that the specific heat is proportional to T at low temperatures. How can the Debye theory be adapted to provide an explanation?

(SUNY, Buffalo)

Statistical Physics 251

Solution:

Graphite is an insulator and its specific heat is contributed entirely by the crystal lattice. When the temperature T increases from zero, the vibrational modes corresponding to the motion between layers is first excited since the coupling between the carbon atoms in different layers is much weaker. By the Debye model, we have

$$\omega = c k$$

The number of longitudinal waves in the interval k to $k+dk$ is $(L/2\pi) \cdot 2\pi k dk$, where L is the length of the graphite crystal. From this, we obtain the

number of the longitudinal waves in the interval ω to $\omega + d\omega$, $L2\pi\omega d\omega / 2\pi c$, where c is the velocity of longitudinal waves. Similarly, the number of

transversal waves in the interval ω to $\omega + d\omega$ is ---,

$$L2\pi\omega d\omega$$

$TC?$

Therefore, the Debye frequency spectrum is given by

$$\omega < \omega_D \text{ (Debye frequency) .}$$

where

$$\hbar \omega_D$$

$\omega_D = \omega_D$, k_B being Boltzmann's constant.

$k_B T$

At low temperatures, $\hbar \omega_D \gg k_B T$, i.e., $x_D \gg 1$, then,

$\propto x_D^{-3}$

where

$x_D = \frac{\hbar \omega_D}{k_B T}$

where

2082

One Dimensional Debye Solid.

Consider a one dimensional lattice of N identical point particles of mass m , interacting via nearest-neighbor spring-like forces with spring constant μ . Denote the lattice spacing by a . As is easily shown, the normal mode eigenfrequencies are given by

$$\omega_k = \omega_D \sqrt{1 - \cos ka}$$

with $k = \frac{2\pi n}{aN}$, where the integer n ranges from $-N/2$ to $+N/2$ ($N \gg 1$). Derive an expression for the quantum mechanical specific heat of this system in the Debye approximation. In particular, evaluate the leading non-zero terms as functions of temperature T for the two limits $T \rightarrow \infty$, $T \rightarrow 0$.

(Princeton)

Solution:

Please refer to Problem 2083.

2083

A one dimensional lattice consists of a linear array of N particles ($N \gg 1$) interacting via spring-like nearest neighbor forces. The normal mode frequencies (radians/sec) are given by

$$\omega_n = \omega_D \sqrt{1 - \cos(2\pi n/N)}$$

where ω_D is a constant and n an integer ranging from $-N/2$ to $+N/2$. The system is in thermal equilibrium at temperature T . Let c_v be the constant "volume" (length) specific heat.

Statistical Physics 253

(a) Compute c_v for the regime $T \rightarrow \infty$.

(b) For $T \rightarrow 0$

$$c_v \rightarrow A \omega_D^{-\gamma} T^{-\beta}$$

where A is a constant that you need not compute. Compute the exponents γ and β .

The problem is to be treated quantum mechanically.

(Princeton)

Solution:

$T \rightarrow \infty$

$$c_v = \frac{1}{2} \sum_{n=-N/2}^{N/2} \hbar \omega_n / k_B T$$

$n=0$ When

$$k_B T \gg \hbar \omega_n$$

$$c_v \approx \frac{1}{2} \sum_{n=-N/2}^{N/2} \hbar \omega_n / k_B T \approx \frac{1}{2} \sum_{n=-N/2}^{N/2} \hbar \omega_n / k_B T$$

$$h\nu_n$$

$$= Nk$$

$$dU$$

Hence $c, = - dT$

(b) When $kT \ll h\nu$, we have

$$Y \approx 1 - N/2$$

$$c_5 \sum_{n=0}^{\infty} C_{n+1} e^{-h\nu_n/kT} = C \sum_{n=0}^{\infty} h\nu_n e^{-h\nu_n/kT} - 1$$

$n=0 \rightarrow n=0$

so

Notice that as $N \gg 1$ we have approximately

$$\sum_{n=0}^{\infty} \sin^2 \left(\frac{n\pi}{N} \right) \approx \frac{N}{2}$$

$$\cos \frac{N\pi}{2}$$

$$N \cdot -d(\sin \frac{y}{N}) \approx dx$$

254 Problems in Statistical Mechanics

Because $\exp(-h\nu/kT)$ decreases rapidly as $\nu \rightarrow 1$, we have

where $A = (16Nk^2/h^2) \int_0^{\infty} \exp(-x) dx$.

Hence $a = 7 = 1$.

2084

Given the energy spectrum

$$E_p = [(pc)^2 + m^2c^4]^{1/2} \approx pc \text{ as } p \rightarrow \infty.$$

(a) Prove that an ultrarelativistic ideal fermion gas satisfies the equation of state $pV = E/3$, where E is the total energy.

(b) Prove that the entropy of an ideal quantum gas is given by

$$S = -k \sum_i [n_i \ln n_i \mp (1 \mp n_i) \ln (1 \mp n_i)]$$

where the upper (lower) signs refer to bosons (fermions).

(SUNY, Buffalo)

Solution:

(a) The number of states in the momentum interval p to $p + dp$ is

$$\frac{8\pi V p^2 dp}{h^3}$$

$F(p) dp$ (taking $S = -$). From $E = cp$, we obtain the number of states in

the energy interval E to $E + dE$:

$$\frac{8\pi V E^2 dE}{c^3 h^3}$$

$$c^3 h^3$$

$$N(E)dE = -e^{-\beta E} dE$$

So the total energy is

Statistical Physics 255

In terms of the thermodynamic potential $\ln Z$,

$$1$$

$$= - \beta E$$

$$3$$

Note that this equation also applies to an ultrarelativistic boson gas.

(b) The average number of particles in the quantum state i is given by

$$n_i = 1 / (\exp(\beta \epsilon_i) \mp 1), \text{ from which we have}$$

or

and

It follows that

i.e., it reduces to the Boltzmann distribution.

258 Problems 4 Solutions on Thermodynamics 6 Statistical Mechanics

- (c) The variation of $\langle N_i \rangle$ versus E_i is as shown in Fig. 2.18.

- (a) $T = K$ (b) $J = \mu - K$

Fig. 2.18.

2087

Suppose that in some sample the density of states of the electrons $D(E)$

is a constant D_0 for energy $E > 0$ ($D(E) = 0$ for $E < 0$) and that the total number of electrons is equal to N .

- (a) Calculate the Fermi potential μ_0 at 0 K.

(b) For non-zero temperatures, derive the condition that the system is

non-degenerate.

(c) Show that the electronic specific heat is proportional to the temperature, T , when the system is highly degenerate. (UC, Berkeley)

Solution:

(a) When $T = 0$ K, all the low lying energy levels are occupied, while those levels whose energies ϵ are greater than μ_0 are all vacant. Taking the $1/2$ spin of electrons into consideration, every state can accommodate two electrons, and hence $2D_0V = N$, or

$$N$$

$$\mu_0 = -2VD_0$$

where V is the volume of the sample.

(b) The non-degeneracy condition requires that $\exp(\beta\epsilon) \ll 1$, then

Statistical Physics

In this approximation,

259

That is, the non-degeneracy condition is $kT \gg (\epsilon_0) / 2 D_0 = \mu_0$.

(c) When $T = 0$ K, the electrons are in the ground state without excitation.

When $T \neq 0$ K, but $T \ll \mu_0 / k$, only those electrons near the Fermi surface are excited, $N_H \approx kT D_0$, and the specific heat contributed by each electron is $C_0 = -k$. Therefore, when the system is highly degenerate, the specific heat $C \propto T$.

3

2088

Consider a system of N "non-interacting" electrons/cm³, each of which can occupy either a bound state with energy $\epsilon = -E_d$ or a free-particle

continuum with $\epsilon = \epsilon_0$. (This could be a semiconductor like Si with N shallow donors/cm³.)

(a) Compute the density of states as a function of ϵ in the continuum.

(b) Find an expression for the chemical potential in the low temperature

(c) Compute the number of free electrons (i.e., electrons in the contin-

(UC, Berkeley)

Suppose that each bound state can at most contain a pair of electrons

N

with anti-parallel spins, and that the number of bound states is N .

2'

is, when $T = 0$ K, all the bound states are filled up with no free electrons.

When T is quite low, only a few electrons are in the free particle continuum so that we can use the approximation of weak-degeneracy.

temperature limit.

um) as a function of T in the low temperature limit.

Solution:

(a) The density of states in the continuum is

(b), (c) The number of electrons in the bound states are

N

$$N_b = e^{-(E_d + \mu)/kT} + 1$$

260 Problems and Solutions on Thermodynamics 6' Statistical Mechanics

The number of electrons in the continuum (weak-degeneracy approximation) is

where

From (1) and (2), we get

Substitute (3) in (2), we get

$N_f - kT N \ln p = kT \ln \dots$
2089

(a) For a system of electrons, assumed non-interacting, show that the probability of finding an electron in a state with energy ϵ above the chemical potential μ is the same as the probability of finding an electron absent from a state with energy ϵ below μ at any given temperature T .

(b) Suppose that the density of states $D(\epsilon)$ is given by

$$D(\epsilon) = \begin{cases} \sqrt{\epsilon - \epsilon_g}, & \epsilon > \epsilon_g \\ 0, & \epsilon < \epsilon_g \end{cases}$$

Statistical Physics 261

as shown in Fig. 2.19,

Fig. 2.19

and that at $T = 0$ all states with $\epsilon < 0$ are occupied while the other states are empty. Now for $T > 0$, some states with $\epsilon > 0$ will be occupied while some states with $\epsilon < 0$ will be empty. If $a = b$, where is the position of μ ?

For $a \neq b$, write down the mathematical equation for the determination of μ and discuss qualitatively where μ will be if $a > b$? $a < b$?

(c) If there is an excess of n_d electrons per unit volume than can be accommodated by the states with $\epsilon < 0$, what is the equation for μ for $T = 0$? How will μ shift as T increases?

(SUNY, Buffalo)

Solution:

needed is

(a) By the Fermi distribution, the probability for a level ϵ to be occupied

the probability for finding an electron at $\epsilon = \mu + \epsilon$ is

and the probability for not finding electrons at $\epsilon = \mu - \epsilon$ is given by

1

$$1 - f(\mu - \epsilon) = e^{-\beta(\mu - \epsilon)}$$

The two probabilities have the same value as required.

(b) When $T > 0$ K, some electrons with $\epsilon < 0$ will be excited to states of $\epsilon > \epsilon_g$. In other words, vacancies are produced in the some states of $\epsilon < 0$

262 Problem 4 Solution on Thermodynamics & Statistical Mechanics

while some electrons occupy states of $\epsilon > \epsilon_g$. The number of electrons with $\epsilon > \epsilon_g$ is given by

The number of vacancies for $\epsilon < 0$ is given by

By $n_v = n - n_e$, we have $\mu = \epsilon_g/2$ when $a = b$. We also obtain the equation to

determine μ when $a \neq b$,

For $a > b$, we have

so that $\mu < \epsilon_g - \mu > \epsilon_g + \mu$, i.e., $\mu < \epsilon_g/2$. μ shifts to lower energies.

For $a < b$, $\mu > \epsilon_g/2$, μ shifts to higher energies.

(c) When $T = 0$, by

we obtain

μ shifts to lower energies as T increases.

Statistical Physics 263

m

m'

$$\text{and } E_F = \frac{p_F^2}{2m} = 5.2 \times 10^{-4} \text{ eV}$$

2091

Calculate the average energy per particle, $\bar{\epsilon}$, for a Fermi gas at $T = 0$,

(UC, Berkeley)

given that E_F is the Fermi energy.

Solution:

We consider two cases separately, non-relativistic and relativistic.

(a) For a non-relativistic particle, $p \ll mc$ (p is the momentum and m is the rest mass), it follows that

$$E = \frac{p^2}{2m}$$

2m

264 Problems in Statistical Mechanics

We have $D(E) = \frac{dN}{dE} = \text{const}$.

Then

$$- \frac{dN}{dE} = \frac{dN}{dE} = \text{const}$$

$$= \frac{dN}{dE} = \text{const}$$

$$\bar{\epsilon} = \frac{\int_0^{E_F} \epsilon D(\epsilon) d\epsilon}{N}$$

(b) For $p \gg mc$, we have $E = pc$, and $D(E) = \frac{dN}{dE} = \text{const}$. Therefore,

2092

Derive the density of states $D(\epsilon)$ as a function of energy ϵ for a free electron gas in one-dimension. (Assume periodic boundary conditions or confine the linear chain to some length L .) Then calculate the Fermi energy E_F at zero temperature for an N electron system.

(Wisconsin)

(Wisconsin)

Solution:

The energy of a particle is $E = \frac{p^2}{2m}$. Thus,

Taking account of the two states of spin, we have

or

$$g(\epsilon) = \frac{2L}{\pi} \frac{1}{\hbar v}$$

At temperature 0 K, the electrons will occupy all the states whose energy

is from 0 to the Fermi energy E_F . Hence

266

giving

2093

Consider a Fermi gas at low temperatures $kT \ll \mu(0)$, where $\mu(0)$

is the chemical potential at $T = 0$. Give qualitative arguments for the

leading value of the exponent of the temperature-dependent term in each of the following quantities: (a) energy; (b) heat capacity; (c) entropy; (d) Helmholtz free energy; (e) chemical potential. The zero of the energy scale is at the lowest orbital.

(UC, Berkeley)

Solution:

At low temperatures, only those particles whose energies fall within a

thickness $\sim kT$ near the Fermi surface are thermally excited. The energy of each such particle is of the order of magnitude kT .

$E - E(0) \propto T^2$.

(a) $E = E(0) + \alpha kT$, where α is a proportionality constant. Hence

G

(c) From $dS = -dT$, we have

T

$S = i \int dT \propto T$.

(d) From $F = E - TS$, we have $F - F(0) \propto T^2$.

(e) From $p = (F + pV)/N$ and $p = 2E/3V$, where N is the total number of particles, we have $p - p(0) \propto T^2$.

2094

Derive an expression for the chemical potential of a free electron gas with a density of N electrons per unit volume at zero temperature ($T = 0$ K). Find the chemical potential of the conduction electrons (which can be considered as free electrons) in a metal with $N = 10^{22}$ electrons/cm³ at $T = 0$ K.

(UC, Berkeley)

Solution:

From the density of states

$D(E) dE = \frac{4\pi}{(2\pi)^3} \frac{m^3}{\hbar^3} \frac{dE}{\hbar} \sim \frac{m^3}{\hbar^3} dE$

we get

$\frac{2m}{\hbar^3} N^{2/3}$

$\frac{2m}{\hbar^3} N^{2/3}$ Therefore, $\mu_0 = -$

For $N = 10^{22}$ electrons/cm³ = 10^{28} electrons/m³, it follows that

$\mu_0 = 2.7 \times 10^{-19}$ J = 1.7 eV.

2095

$D(E)$ is the density of states in a metal, and E_F is the Fermi energy.

At the Fermi energy $D(E_F) \neq 0$.

(a) Give an expression for the total number of electrons in the system at temperature $T = 0$ in terms of E_F and $D(E_F)$.

(b) Give an expression of the total number of electrons in the system at $T \neq 0$ in terms of the chemical potential μ and $D(E)$.

(c) Calculate the temperature dependence of the chemical potential at low temperatures, i.e., $\mu \gg kT$.

(Chicago)

Statistical Physics 267

Fig. 2.20.

Solution:

The density of states is

Statistical Physics 269

2097

The electrons in a metallic solid may be considered to be a three-dimensional free electron gas. For this case:

(a) Obtain the allowed values of k_x, k_y, k_z and sketch the appropriate Fermi sphere in k -space. (Use periodic boundary conditions with length L).

(b) Obtain the maximum value of k for a system of N electrons, and hence an expression for the Fermi energy at $T = 0$ K.

(c) Using a simple argument show that the contribution the electrons make to the specific heat is proportional to T .

Solution:

(a) The periodic condition requires that the length of the container L is an integral multiple of the de Broglie wavelength for the possible states of motion of the particle, that is,

(Wisconsin)

$$L = n\lambda, \quad n = 0, 1, 2, \dots$$

Utilizing the relation between the wavelength and the wave vector, $k = 2\pi/\lambda$, and taking into account the two propagating directions for each dimension, we obtain the allowed values of k_x ,

2s

$$k_x = \frac{n\pi}{L}, \quad n = 0, 1, 2, \dots$$

Similarly we have

Thus the energies

$$E = \frac{\hbar^2 k^2}{2m}$$

2m

are discrete. The Fermi sphere shell is shown in Fig. 2.21.

270 Problems and Solutions on Thermodynamics and Statistical Mechanics

L

2π

$$(b) \quad dn_x = -dk_x,$$

$$L \, dn_x = -L \, dk_x,$$

$$dn_x = -dk_x.$$

2T

2.n

Thus, in the volume $V = L^3$, the number of quantum states of free

electrons in the region $k_x \rightarrow k_x + dk_x, k_y \rightarrow k_y + dk_y, k_z \rightarrow k_z + dk_z$ is (considering the two directions of spin)

$$dN = 2 \, dn_x \, dn_y \, dn_z = 2 \, dk_x \, dk_y \, dk_z.$$

$$= 4\pi k^2 \, dk$$

At $T = 0 \text{ K}$, the electrons occupy the lowest states. According to the Pauli exclusion principle, there is at most one electron in a quantum state. Hence so that

113

$$k_{F,0} = (3\pi^2 n)^{1/3}.$$

The Fermi energy is

(c) At $T = 0 \text{ K}$, the electrons occupy all the quantum states of energies from 0 to E_F . When the temperature is increased, some of the electrons can be excited into states of higher energies that are not occupied, but they must absorb much energy to do so, so that the probability is very small.

Thus the occupancy situation of most of the states do not change, except those with kT near the Fermi energy E_F . Therefore, only the electrons in such states contribute to the specific heat. Let N_f denote the number of such electrons, we have $N_f R = kT N_f / E_F$. Thus the molar specific heat contributed by the electrons is

Statistical Physics 271

2098

Sketch the specific heat curve at constant volume, C_v , as a function of the absolute temperature, T , for a metallic solid. Give an argument showing why the contribution to C_v from the free electrons is proportional to T .

(*wisconsin*)

Solution:

As shown in Fig. 2.22, the specific heat of a metal is

$$C_v = \gamma T + \beta T^3$$

where the first term on the right hand side is the contribution of the free electrons and the second term is the contribution of lattice oscillation.

T2

2102

Fermi gas. Consider an ideal Fermi gas whose atoms have mass $m =$

5.8 grams, nuclear spin $I = \frac{1}{2}$, and nuclear magnetic moment $\mu =$

1.8 erg/gauss. At $T = 0 \text{ K}$, what is the largest density for which the

gas can be completely polarized by an external magnetic field of 105 gauss?

(Assume no electronic magnetic moment).

Solution:

(MZT)

After the gas is completely polarized by an external magnetic field, the

Fermi energy is $\epsilon_F = \frac{1}{2} (2\pi^2 n)^{2/3} \frac{\hbar^2}{2m}$, where n is the particle density.

$2m$

With $\epsilon_F = \frac{1}{2} \mu H$, we have

$1 \frac{1}{2} \mu H = \frac{1}{2} (2\pi^2 n)^{2/3} \frac{\hbar^2}{2m}$

$n \propto H^3$.

Hence, $n_{\text{max}} = 2 \times 10^{23} \text{ atoms/cm}^3$.

2103

State and give a brief justification for the leading exponent n in the temperature dependence of the following quantities in a highly degenerate three-dimensional electron gas:

(a) the specific heat at constant volume;

(b) the spin contribution to the magnetic moment M in a fixed magnetic

field H .

(MITI)

Solution:

Let us first consider the integral I :

Statistid Physic8 277

where $kTz = -\mu + \epsilon$. As $\mu/kT \gg 1$, we can substitute ∞ for the upper limit of the second integral in above expression so that

(a) Let $f(\epsilon) = c_1 T^2$, then the internal energy $E = I$, $C_v = -$

T i.e., $n = 1$. In fact, when $T = 0$ K, because the heat energy is so small, only those electrons which lie in the transition band of width about kT on

the Fermi surface can be excited into energy levels of energies $\approx kT$. The part of the internal energy directly related to T is then

$$(\ : IV$$

$NT \approx T^2$, i.e., $C_v \approx T$.

(b) Let $f(\epsilon) \sim \epsilon^2$, then $M = I$, hence $M = M_0(1 - aT^2)$, i.e., $n = 0$.

When $T = 0$ K, the Fermi surface EF with spin direction parallel to \mathbf{H} is $\epsilon_{F\uparrow} = \mu + \mu_B H$ (μ_B is the Bohr magneton) while the Fermi surface EF with spin direction opposite to \mathbf{H} is $\epsilon_{F\downarrow} = \mu - \mu_B H$. Therefore, there exists a net spin magnetic moment parallel to \mathbf{H} . Hence $n \neq 0$.

2104

electrons in a "box" of volume $V =$

1 cm^3 . The walls of the box are infinitely high potential barriers. Calculate the following within a factor of five and show the dependence on the relevant physical parameters:

Take a system of $N = 2 \times 10^{23}$

(a) the specific heat, C_v ,

(b) the magnetic susceptibility, χ ,

(c) the pressure on the walls of the box, p ,

(d) the average kinetic energy, $\langle Ek \rangle$.

(Cham g 0)

Solution:

The density of states in \mathbf{k} space is given by

$$4\pi k^2$$

$$\frac{8\pi}{(2\pi)^3} dk^3$$

$$D(k)dk = \frac{2V}{\pi^2} k^2 dk$$

278 Problems & Solutions on Thermodynamics & Statistical Mechanics

N

(c) The pressure is
 $2N^2$

$\tau \approx \rho(0) \alpha v$

(d) For $\rho(0) > \sim B H$, the magnetization is given by

$$\mathbf{M} = \frac{p_g(N_- - N_+)}{V} = -\frac{3\mu_B N H}{x H}$$

$$2P(0)V$$

$$3N\mu_B$$

$$2P(0)V$$

Hence $\chi = -$

2106

Consider a Fermi gas model of nuclei.

Except for the Pauli principle, the nucleons in a heavy nucleus are assumed to move independently in a sphere corresponding to the nuclear volume V . They are considered as a completely degenerate Fermi gas. Let $A = N$ (the number of neutrons) + Z (the number of protons), assume $N = 2$, and compute the kinetic energy per nucleon, E_{kin}/A , with this model.

Statistical Physica **281**

4s

3

The volume of the nucleus is given by $V = \frac{4}{3}\pi R^3$, $R = r_0 A^{1/3}$

Please give the result in MeV.

cm.

(Chicago)

Solution:

In the momentum space,

4v

$$h^3 dn = 4\pi n^2 dp$$

where n is the number density of neutrons.

The total number of neutrons is

$$A = \int_0^{p_F} 4\pi n^2 dp = \frac{4\pi}{3} n^3 \left(\frac{h}{2\pi}\right)^3 V$$

where p_F is the Fermi momentum.

The total kinetic energy of the neutrons is

Hence ,

The volume V can be expressed in two ways:

$$V = \frac{4\pi}{3} \left(\frac{h}{2\pi}\right)^3 n^3 = \frac{4\pi}{3} \left(\frac{h}{2\pi}\right)^3 \left(\frac{3A}{4\pi}\right)^{3/3} = \frac{h^3}{2\pi^2} A$$

$$3 \cdot 0 \cdot 16n \cdot 27r$$

giving $p_F = R \cdot \left(\frac{2}{3}\right)^{1/3}$, and

282 Problems & Solutions in Thermodynamics & Statistical Mechanics

2107

At low temperatures, a mixture of ^3He and ^4He atoms form a liquid which separates into two phases: a concentrated phase (nearly pure ^3He), and a dilute phase (roughly 6.5% ^3He for $T \lesssim 0.1$ K). The lighter ^3He floats on top of the dilute phase, and ^3He atoms can cross the phase boundary (see Fig. 2.23).

The superfluid ^4He has negligible excitation, and the thermodynamics of the dilute phase can be represented as an ideal degenerate Fermi gas of particles with density n and effective mass m^* (m^* is larger than m , the mass of the bare ^3He atom, due to the presence of the liquid ^4He , actually $m^* = 2.4m$). We can crudely represent the concentrated phase by an ideal

degenerate Fermi gas of density n , and particle mass m .

(a) Calculate the Fermi energies for the two fluids.

(b) Using simple physical arguments, make an estimate of the very low temperature specific heat of the concentrated phase $c_c(T, T_F \sim \text{w})$ which explicitly shows its functional dependence on T and T_F , (where T_F is the Fermi temperature of the concentrated phase, and any constants independent of T and T_F , need not be determined). Compare the specific heats of the dilute and concentrated phases.

(c) How much heat is required to warm each phase from $T = 0$ K to T ?

Fig. 2.23 concentrated phase of ^3He

dilute phase of ^3He
(in superfluid of ^3He)

Fig. 2.23.

(d) Suppose the container in the figure is now connected to external plumbing so that ^3He atoms can be transferred from the concentrated phase to the dilute phase at a rate of N , atoms per second (as in a dilution refrigerator). For fixed temperature T , how much power can this system absorb?

T_F

$= \frac{A}{T}$, where A is a constant.

The power absorbed is converted to latent heat, being

2108

A white-dwarf star is thought to constitute a degenerate electron gas system at a uniform temperature much below the Fermi temperature. This system is stable against gravitational collapse so long as the electrons are non-relativistic.

(a) Calculate the electron density for which the Fermi momentum is one-tenth of the electron rest mass $m_e c$.

(b) Calculate the pressure of the degenerate electron gas under these conditions.

(UC, Berkeley)

284 Problems in Statistical Mechanics

Solution:

$p \ll pc$

... giving $n = \dots$

With

mc

$p = F = -10$

we have

$8r = m, c^3$

$$n = 7 \left(\frac{\dots}{\dots} \right) = 5.8 \times 10^{31} / m^3$$

(b) For a strong degenerate Fermi gas (under the approximation of zero valence), we get

$$-3E = -Np_0, 5$$

and

$$p = 2P; = -n = 9.5 \times 10^{31} \text{ N/m}^2 \cdot p = -2E = -2n$$

$3 \times 10^{31} \text{ m}$

2109

A white dwarf is a star supported by the pressure of degenerate electrons.

As a simplified model for such an object, consider a sphere of an ideal gas consisting of electrons and completely ionized Si₂₈, and of constant density throughout the star. (Note that the assumption of a constant density is inconsistent with hydrostatic equilibrium, since the pressure is then also constant. The assumption that the gas is ideal is also not really tenable. These shortcomings of the model are, however, not crucial for the issues which we wish to consider.) Let n_i denote the density of the silicon ions, and let $n_e = 14n_i$ denote the electron density. (The atomic number of silicon is 14).

(a) Find the relation between the mean kinetic energy E_e of the electrons and the density n_e , assuming that the densities are such that the electrons are "extremely relativistic," i.e., such that the rest energy is negligible compared with the total energy.

(b) Compute E_e (in MeV) in the case that the (rest mass) density of the gas equals $\rho = 10^9 \text{ g/cm}^3$. Also compute the mean kinetic energy E_i of the silicon ions in the central region of the dwarf, assuming that the temperature is 10^8 K and assuming that the 'ion gas' can be regarded as a Maxwell-Boltzmann gas, and hence convince yourself that $E_e \gg E_i$.

(c) If M is the mass of the star, and if R is its radius, then the gravitational potential energy is $U = -3GM^2/5R$.

In the case in which the internal energy is dominated by extremely relativistic electrons (as in part (b) above), the virial theorem implies that the total internal energy is approximately equal to the gravitational potential energy. Assuming equality, and assuming that the electrons do not contribute significantly to the mass of the star, show that the stellar mass can be expressed in terms of fundamental physical constants alone. Evaluate your answer numerically and compare it with the mass of the sun, $2 \times 10^{30} \text{ kg}$. (It can be shown that this is approximately the maximum possible mass of a white dwarf.)

(UC, Berkeley)

Solution:

(a) Use the approximation of strong degenerate electron gas and $\epsilon = pc$. From the quantum state density of electrons, it follows that the total potential energy is given by

$$U = -\frac{3}{5} \frac{GM^2}{R}$$

$2 \times 10^{30} \text{ kg}$

$-dp = -E2ds, h^3 h^3 c^3$
then

$$n = \frac{1}{h^3} \int \frac{2 \pi^2 E^{3/2}}{4 \pi^2 m^3} \frac{1}{e^{\beta(E - \mu)}} d^3 p$$

Therefore

(b) When $\rho = 10^9 \text{ g/cm}^3$,
 $n = 14 n_i = 3 \times 10^{32} \text{ m}^{-3} = 3 \times 10^{26} \text{ cm}^{-3}$
 $E_f = 5 \text{ MeV}$
 $E_i = -kT = 2 \text{ eV}$

$m^{-1}, -$
 $J = 3 \text{ MeV},$
 3
 2
 $-$
 $J = 1.3 \sim 10^{-10} \text{ MeV}.$

Obviously, $\mu \ll E_f$.
286 Problems Solutions on *Thermodynamics* & *Statistical Mechanics*

(c) From the virial theorem, we have
 $(\frac{3}{2} N k T) = \frac{1}{2} M v^2 \sim \frac{1}{2} G M^2 / R$

we obtain
 $M = \frac{3}{2} \frac{N k T R}{G M} = 8.5 \times 10^3 \text{ kg} = 4.1 M_\odot,$

$1.28 \sim G m$,
 where M_\odot is the mass of the sun.

- 2110**
 (a) Given that the mass of the sun is $2 \times 10^{30} \text{ kg}$, estimate the number of electrons in the sun. Assume the sun is largely composed of atomic hydrogen.
 (b) In a white dwarf star of one solar mass the atoms are all ionized and contained in a sphere of radius $2 \times 10^9 \text{ cm}$. Find the Fermi energy of the electrons in eV.
 (c) If the temperature of the white dwarf is 10^8 K , discuss whether the electrons are degenerate.
 (d) If the above number of electrons were contained in a pulsar of one solar mass and of radius 10 km , find the order of magnitude of their Fermi energy.

(Columbia)
 electrons and/or nucleons in the star are degenerate.
 Solution:

(a) The number of electrons is
 $1.2 \times 10^{57} \cdot 2 \times 10^{30}$
 1.67×10^{-24}
 $N =$
 (b) The Fermi energy of the electrons is
 $E_F = 4 \times 10^4 \text{ eV} \cdot E_F = \frac{h^2}{2m} (3\pi^2 N)^{2/3} = 9 N^{2/3}$
 $2m, 32 \times 2 R^3$

Statistical Physics 287
 The Fermi energy of the nucleons is
 $E_F \sim m_e c^2 = E_F e = -E_F e \cdot m, 1840$

(c) $EF_c/k = 4 \times 10^8 \text{ K} > 10^7 \text{ K}$.

$EF_c/k \ll 10^7 \text{ K}$.

Therefore, in a white dwarf, the electrons are strongly degenerate while the nucleons are weakly degenerate.

(d) The Fermi energy of the electrons if contained in a pulsar is

2111

At what particle density does a gas of free electrons (considered at $T = 0 \text{ K}$) have enough one-particle kinetic energy (Fermi energy) to permit the reaction

proton + electron + 0.8 MeV \rightarrow neutron

to proceed from left to right? Using the result above estimate the minimum density of a neutron star.

(UC, Berkeley)

Solution:

electron gas are related as follows:

When $T = 0 \text{ K}$, the Fermi energy and the number density of the

The condition for the reaction to proceed is $EF \geq 0.8 \text{ MeV}$, then

$$n_{\text{min}} = 3.24 \times 10^3 \text{ m}^{-3}$$

Hence the minimum mass density of a neutron star is

$$\rho_{\text{min}} = m_p n_{\text{min}} = 5.4 \times 10^9 \text{ kg/m}^3$$

288 Problems in Statistical Mechanics

2112

Assume that a neutron star is a highly degenerate non-relativistic gas of neutrons in a spherically symmetric equilibrium configuration. It is held together by the gravitational pull of a heavy object with mass M and radius r_0 at the center of the star. Neglect all interactions among the neutrons.

Calculate the neutron density as a function of the distance from the center, r , for $r > r_0$.

(Chicago)

Solution:

For a non-relativistic degenerate gas, the density ρ is $\rho = \frac{2}{3} \frac{p}{\mu}$, the pressure p is $p = \frac{2}{3} \mu \rho$, where μ is the chemical potential. Therefore, $p = \frac{2}{3} \mu \rho$, where μ is a constant. Applying it to the equation

$$-dp = \rho g dr$$

ρ

5

2

we find $\rho = \frac{2}{3} \frac{p}{\mu} = \frac{2}{3} \frac{a \mu^2}{3} = \frac{2}{9} a \mu^2$

$$p(r) = \left[-\frac{2}{9} M a G r^{-1} + \text{const} \right] \frac{3}{2} \mu$$

As $r \rightarrow \infty$, $p(r) \rightarrow 0$, we find $\text{const} = 0$. Finally, with $r > r_0$, we have $\rho = \frac{2}{9} \frac{2}{3} M a G r^{-2} = \frac{4}{27} M a G r^{-2}$

$$P(r) = \left[\frac{2}{9} M a G r^{-2} \right] \frac{3}{2} \mu$$

2113

Consider a degenerate (i.e., $T = 0 \text{ K}$) gas of N non-interacting electrons in a volume V .

(a) Find an equation relating pressure, energy and volume of this gas for the extreme relativistic case (ignore the electron mass).

(b) For a gas of real electrons (i.e., of mass m), find the condition on N and V for the result of part (a) to be approximately valid.

(MIT)

Statistical Physics 289

Solution:

The energy of a non-interacting degenerate electron gas is:

$$E = \int_0^p \epsilon(p) g(p) dp$$

$$E = \int_0^p \epsilon(p) g(p) dp$$

where ϵ is the energy of a single electron, p is the Fermi momentum,

$$p_F = \left(\frac{3N}{8\pi} \right)^{1/3} \hbar$$

(a) For the extreme relativistic case, $\epsilon = cp$, so we have energy

$$E = \int_0^p cp g(p) dp$$

which gives the equation of state

$$p = \frac{1}{3} \frac{E}{V}$$

$$pV = \frac{1}{3} E$$

$$pV = \frac{1}{3} E$$

$$pV = \frac{1}{3} E$$

(b) For a real electron,

where p is its momentum, giving

$$E = \int_0^p \sqrt{m^2c^4 + p^2c^2} g(p) dp$$

The condition for the result of part (a) to be approximately valid is $pc \gg mc$ or

$$N \gg \left(\frac{mc}{\hbar v} \right)^3 V$$

Either $N \rightarrow \infty$ or $V \rightarrow 0$ will satisfy this condition.

2114

Consider a box of volume V containing electron-positron pairs and

photons in equilibrium at a temperature $T = 1/k\beta$. Assume that the equilibrium is established by the reaction

290 Problem 8.4 Solution on Thermodynamics 4 Statistical Mechanics

The reaction does not occur in free space, but one may think of it as catalyzed by the walls of the box. Ignoring the walls except insofar as they allow the reaction to occur, find

(a) The chemical potentials for the fermions.

(b) The average number of electron-positron pairs, in the two limits

$kT \gg mc^2$ and $kT \ll mc^2$. (You may leave your answers in terms of dimensionless definite integrals.)

(c) The neglect of the walls is not strictly permissible if they contain a matter-antimatter imbalance. Supposing that this imbalance creates a net chemical potential $\mu \neq 0$ for the electrons, what is then the chemical potential of the positrons?

(d) Calculate the net charge of the system in the presence of this imbalance in the limit $kT \gg \mu \gg mc^2$. (Again, your answer may be left in terms of a dimensionless definite integral.)

(Chicago)

Solution:

(a) For a chemical reaction $A \leftrightarrow B + C$ at equilibrium, $\mu = \mu_B + \mu_C$.

As the chemical potential of the photon gas $\mu_\gamma = 0$, we obtain

$$\mu_{e^+} + \mu_{e^-} = 0$$

Considering the symmetry between particle and antiparticle, we have

$$\mu_{e^+} = \mu_{e^-} = 0$$

(b) At the limit $kT \gg mc^2$, neglecting the electron mass and letting

$$E = cp$$

$$V(kT)^3 \int_0^\infty x^2 dx$$

$$\frac{7\pi^2 (h)^3}{6} e^{\mu/kT} \int_0^\infty x^2 dx = N e^{\mu/kT}$$

At the limit $kT \ll mc^2$, the "1" in denominator of the Fermi factor

$$\frac{1}{1 + e^{(mc^2 - \epsilon)/kT}} \approx e^{-(mc^2 - \epsilon)/kT}$$

can be neglected and we also have

$$\mu = \frac{1}{2} (kT)^2 \ln \left(\frac{N}{V} \left(\frac{2\pi m kT}{h^2} \right)^{3/2} \right)$$

Thus

$$\mu = kT \ln \left(\frac{N}{V} \left(\frac{2\pi m kT}{h^2} \right)^{3/2} \right)$$

$$(c) \mu_{e^+} + \mu_{e^-} = 0, \mu_{\nu} = -\mu_{\bar{\nu}} = -\mu$$

(d) The net charge of the system is $q = (-e)(n_{e^-} - n_{e^+})$, where

$$n = \frac{8\pi V}{h^3} \int_0^\infty x^2 dx$$

2115

In the very early stages of the universe, it is usually a good approximation to neglect particle masses and chemical potential compared with

kT .

(a) Write down the average number and energy densities of a gas of non-interacting fermions in thermal equilibrium under these conditions.

(You need not evaluate dimensionless integrals of order 1.)

(b) If the gas expands adiabatically while remaining in equilibrium, how do the average number and energy densities depend on the dimensions of the system?

when $T \sim 10^{11}$ K in parts (c) and (d) below.

Assume that the fermions are predominantly electrons and positrons

(c) Is the assumption made in (a) that the particles are non-interacting reasonable? Why? [Hint: What is the average coulomb interaction energy?

292 Problems & Solutions on Thermodynamics B Statistical Mechanics

Positron charge = 1.6×10^{-19} coulomb; Boltzmann's constant $k = 1.38 \times 10^{-16}$ erg/K].

(d) If the interaction cross sections in the electron-positron gas are typically of order of magnitude of the Thompson cross section $\sigma_T = 8\pi/3$ (classical electron radius $r_0 = 2.8 \times 10^{-8}$ cm), estimate the mean free time between collisions of the particles. If the expansion rate in part (b) is

10^4 sec⁻¹, is the assumption that the gas remains in equilibrium reasonable?

Why?

(SUIVY, Buffalo)

Solution:

(a) In the stated approximation, we have

$$P = \frac{1}{3} \rho c$$

$$kT = \frac{1}{3} \rho c$$

$$\rho = 3kT/c$$

so

The average number density is

The average energy density is

(b) The quasi-static adiabatic expansion process satisfies the equation $d(pV) = -pdV$. Neglecting the particle mass, we have $p = \rho/3$ (analogous to a photon gas), then

$$-dp - 4 dV$$

$$P = 3 \rho V$$

giving

from which we obtain $T \propto V^{-1/3}$.

$n \propto V^{-1}$.

$p \propto v^{-4/3}$,

Hence the particle number density

(c) The average distance between particles $r \propto n^{-1/3}$. The ratio of the Coulomb interaction energy per particle to the particle kinetic energy is $e^2/r \propto n^{1/3} \propto V^{-1/3}$.

$kT \propto hc^{-1} \approx 137^{-1}$.

Statistical Physics 293

This implies that the interaction energy is much less than the kinetic energy, which makes the approximation in (a) reasonable.

(d) The mean free time is $t \approx l/nqv$, where the average speed $v \propto \sqrt{kT}$.

Hence $t \approx (E)^{-3/2} \approx 10^{-23}$ s.

The assumption that the gas remains in equilibrium is reasonable for the mean free time is much shorter than the expansion time which is of the order of 10^{-4} s.

4. ENSEMBLES (2116 - 2148)

2116

Heat Capacity.

The constant volume heat capacity of a system with average energy

$\langle E \rangle$ is given by $C_v = \frac{d\langle E \rangle}{dT}$.

Use the canonical ensemble to prove that C_v is related to the mean square fluctuation in the energy as follows:

Solution:

The partition function is

$$Z = \sum_i \exp(-E_i/kT).$$

1

Therefore, $\langle E \rangle = -\frac{1}{Z} \frac{dZ}{d\beta}$, where $\beta = 1/kT$. Then

monatomic gas.

(e) For an ideal monatomic gas,

$E = 3/2 NkT$

$$E = 3/2 NkT$$

$$\Delta E = \sqrt{3/2} Nk$$

and thus

$$\frac{\Delta E}{E} = \sqrt{2/3}$$

296 Problems 6' Solution on Thermodynamics 6' Statistical Mechanics

2119

A useful way to cool He3 is to apply pressure P at sufficiently low temperature T to a co-existing liquid-solid mixture. Describe qualitatively how this works on the basis of the following assumptions:

(a) The molar volume of the liquid V_L is greater than that of the solid V_s at all temperatures.

(b) The molar liquid entropy is given by

$$S_L = 7RT \ln T + 4.6 R$$

(c) The entropy of the solid S_s comes entirely from the disorder associated with the nuclear spins ($s = 1/2$).

Note: Include in your answer a semi-quantitative graph of the p-T diagram of He3 at low temperatures (derived using the above information).

(Chicago)

Solution:

The Clausius-Clapeyron equation is

$$\frac{dp}{dT} = \frac{S_L - S_s}{V_L - V_s}$$

$$= \frac{7R \ln T + 4.6R - S_s}{V_L - V_s}$$

1
 1z
Tmin T

the pressure reaches the minimum value. This means that at sufficiently low temperatures ($T < T_{min}$), applying compression can lead to a decrease in temperature of the solid-liquid mixture.

A semi-quantitative p - T diagram of He3 at low temperatures is shown in Fig. 2.24.

2120

- (a) Describe the third law of thermodynamics.
- (b) Explain the physical meaning of negative absolute temperature. Does it violate the third law? Why?
- (c) Suggest one example in which the negative temperature can actually be achieved.
- (d) Discuss why the negative temperature does not make sense in classical thermodynamics.

(S *VNY, Buflulo*)

Solution:

can have its absolute temperature reduced to zero.

- (a) The third law or the Nernst heat theorem signifies that no system
- (b) According to the Gibbs distribution, at equilibrium the ratio of the particle number of energy level E_n to that of E_m is $N_n/N_m = \exp[-(E_n - E_m)/kT]$. Hence, the particle number in the higher energy level is smaller than that in the lower energy level for $T > 0$. If the reverse is the case, i.e., under population inversion, the equation requires $T < 0$ and the system is said to be at negative temperature. This does not violate the third law for a system at negative temperature is further away from absolute zero than a system at positive temperature, from the point of view of energy.

1

2

- (c) One such example is a localized system of spin - particles. We can introduce a strong magnetic field to align all the spins in the same direction as, i.e., parallel to, the direction of the magnetic field. We then reverse the magnetic field quickly so that there is no time for most of the spins to change direction. Thus negative temperature is achieved.
- (d) In classical thermodynamics, a negative temperature system is mechanically unstable. We divide a substance at rest into several parts. Let the internal energy and entropy of part z be U_z and $S_z(V_z)$ respectively. We have where E_z is the total energy of the part, M_z is its mass, and p_z is its

momentum with $\mathbf{xp}, = 0$. Mechanical equilibrium requires all $\mathbf{p}; = 0$.

As we have for a negative temperature system $dS;(U;)/dU; = 1/T < 0$, S , will increase when U , decreases, i.e., p , increases. Thus the entropies $S;(U)$ are maximum when the $1p;l's$ reach maximum. This contradicts the mechanical equilibrium condition $\mathbf{p}; = 0$.

2121

Consider a system of two atoms, each having only 3 quantum states of energies 0, ϵ and 2ϵ . The system is in contact with a heat reservoir at temperature T . Write down the partition function Z for the system if the particles obey

- (a) Classical statistics and are distinguishable.
- (b) Classical statistics and are indistinguishable.
- (c) Fermi-Dirac statistics.
- (d) Bose-Einstein statistics.

(SUNY, Buffalo)

Solution:

- (a) $Z1 = A^2$, where $A = 1 + \exp(-P\epsilon) + \exp(-2P\epsilon)$.
- (c) $Z3 = A \exp(-pe)$.
- (d) $Z, = A (1 + \exp(-ZP\epsilon))$.

(a) You are given a system of two identical particles which may occupy any of the three energy levels

$$\epsilon_n = n \epsilon, n = 0, 1, 2, \dots$$

The lowest energy state, $\epsilon_0 = 0$, is doubly degenerate. The system is in thermal equilibrium at temperature T . For each of the following cases determine the partition function and the energy and carefully enumerate the configurations.

- 1) The particles obey Fermi statistics.
 - 2) The particle obey Bose statistics.
 - 3) The (now distinguishable) particles obey Boltzmann statistics.
- (b) Discuss the conditions under which Fermions or Bosons may be treated as Boltzmann particles.

(SVNY, Buflalo)

Solution:

(a) Considering the systems as a canonical ensemble, the partition function is $z = \sum_n w_n \exp(-P E_n)$, where w_n , is the degeneracy of energy level n .

- 1) The particles obey Fermi statistics. We have
The configurations are shown in Fig. 2.25(a)

kT where $P = -$.

(c) For a system with one excited state at energy A above the ground state, find an expression for the heat capacity in terms of A . Sketch the dependence on temperature and discuss the limiting behavior for high and low temperatures.

(UC, Berkeley)

Solution:

(a) The partition function is the sum of statistical probabilities.

For quantum statistics, $z = \sum_s e^{-\beta E_s}$, summing over all the quantum states.

For classical statistics, $z = \frac{1}{h^{\gamma}} \int e^{-\beta E} d\Gamma$, integrating over the phase-space where γ is the number of degrees of freedom.

$\frac{d \ln z}{d\beta} = -\langle E \rangle$

$\frac{d \ln z}{d\beta} = -\langle E \rangle$

$\frac{d \ln z}{d\beta} = -\langle E \rangle$

$\frac{d \ln z}{d\beta} = -\langle E \rangle$

$\frac{d \ln z}{d\beta} = -\langle E \rangle = -\frac{1}{z} \sum_s E_s e^{-\beta E_s}$

$\frac{d \ln z}{d\beta} = -\langle E \rangle$

(c) Assume the two states are non-degenerate, then

Consider a collection of N two-level systems in thermal equilibrium at a temperature T . Each system has only two states: a ground state of energy 0 and an excited state of energy E . Find each of the following quantities and make a sketch of the temperature dependence.

- (a) The probability that a given system will be found in the excited state.
- (b) The entropy of the entire collection.

(MIT)

Solution:

- (a) The probability for a system to be in the excited state is $P = \frac{e^{-E/kT}}{1 + e^{-E/kT}}$

where $z = 1 + e^{-E/kT}$, i.e.,

The relation between probability and temperature is shown in Fig. 2.27.

- (b) $S = -k \ln z^N$, $F = -kT \ln z^N$

Statistical Physics 303

The relation between entropy and temperature is shown in Fig. 2.28.

(Fig. 2.28.)

2125

N weakly coupled particles obeying Maxwell-Boltzmann statistics may each exist in one of the 3 non-degenerate energy levels of energies $-E$, 0, $+E$. The system is in contact with a thermal reservoir at temperature T .

- (a) What is the entropy of the system at $T = 0$ K?
- (b) What is the maximum possible entropy of the system?
- (c) What is the minimum possible energy of the system?
- (d) What is the partition function of the system?
- (e) What is the most probable energy of the system?

(f) If $C(T)$ is the heat capacity of the system, what is the value of $\int_0^T C(T) dT$?

o T

(UC, Berkeley)

Solution:

- (a) At $T = 0$ K, the entropy of the system is $S(0) = 0$.

- (b) The maximum entropy of the system is

$$S_{max} = k \ln 3^N = N k \ln 3$$

- (c) The minimum energy of the system is $-NE$.

- (d) The partition function of the system is

$$Z = (e^{E/kT} + 1 + e^{-E/kT})^N$$

304 Problems in Statistical Mechanics

- (e) When $N \gg 1$, the most probable energy is the average energy

$$NE$$

$$S = Nk \ln \left(\frac{1 + 2 \cosh(a)}{3} \right)$$

$$S = Nk \ln \left(\frac{1 + 2 \cosh(a)}{3} \right)$$

where $a = E/kT$.

- (f) $\int_0^T C(T) dT = S(T) - S(0) = Nk \ln 3$

2126

Find the pressure, entropy, and specific heat at constant volume of an ideal Boltzmann gas of indistinguishable particles in the extreme relativistic limit, in which the energy of a particle is related to its momentum by $\epsilon = cp$. Express your answer as functions of the volume V , temperature T , and number of particle N .

(Princeton)

Solution:

Let z denote the partition function of a single particle, Z the total partition function, p the pressure, S the entropy, U the internal energy, and c the specific heat. We have

$$p = \frac{8}{3} \frac{U}{V}$$

N

Statistical Physics 305

a

$$p = \frac{8}{3} \frac{U}{V} = - \frac{1}{V} \ln Z = \frac{3NkT}{V}$$

$$c = 3 N k .$$

2127

A vessel of volume V contains N molecules of an ideal gas held at temperature T and pressure P_1 . The energy of a molecule may be written in the form

where ϵ_k denotes the energy levels corresponding to the internal states of the molecules of the gas.

(a) Evaluate the free energy $F = -kT \ln Z$, where Z is the partition function and k is Boltzmann's constant. Explicitly display the dependence on the volume V .

Now consider another vessel, also at temperature T , containing the same number of molecules of an identical gas held at pressure P_2 .

(b) Give an expression for the total entropy of the two gases in terms of P_1, P_2, T, N .

(c) The vessels are then connected to permit the gases to mix without doing work. Evaluate explicitly the change in entropy of the system. Check whether your answer makes sense by considering the special case $V_1 = V_2$ (i.e., $P_1 = P_2$).

(Princeton)

Solution:

(a) The partition function of a single particle is where $\epsilon_k = \exp(-\epsilon_k/kT)$ refers to the internal energy levels. Taking account of the indistinguishability of the particles, the partition function of

N SO6 Problems and Solutions on Thermodynamics and Statistical Mechanics

the N particle system is

so

$$F = -kT \ln Z$$

Thus

$$S = Nk \left(\frac{U}{kT} + \ln \left(\frac{V}{N} \right) \right) + S_0,$$

where a

$$a = \ln \left(\frac{U}{kT} \right) - \ln \left(\frac{V}{N} \right)$$

The total entropy is

$$S = S_1 + S_2,$$

$$= 2Nk \left[\ln \frac{N}{N} + \frac{3}{2} \ln \left(\frac{2\pi m k T}{h^2} \right) + \frac{5}{2} \right]$$

(c) After mixing, the temperature of the ideal gas is the same as before, so that

$$S' = 2Nk \left[\ln \left(\frac{2V}{V} \right) + \frac{3}{2} \ln \left(\frac{2\pi m k T}{h^2} \right) + \frac{5}{2} \right]$$

Statistical Physics 307

When $V_1 = V_2$, $\Delta S = 0$ as expected.

2128

(a) Calculate the partition function z of one spinless atom of mass M moving freely in a cube of volume $V = L^3$. Express your result in terms of the quantum concentration

$$\frac{MkT}{2\pi h^2}$$

$n_q = \left(\frac{MkT}{2\pi h^2} \right)^{3/2}$

Explain the physical meaning of n_q .

(b) An ideal gas of N spinless atoms occupies a volume V at temperature T . Each atom has only two energy levels separated by an energy ϵ . Find the chemical potential, free energy, entropy, pressure and heat capacity at constant pressure.

Solution:

(SVNY, Buflulo)

(a) The energy eigenvalues are given by

$$\frac{h^2 k^2}{2M}$$

$$\frac{2mL^2 k^2}{2M}$$

$$\frac{2M}{h^2}$$

$$s = -k \ln Z = -k \ln \left(\sum_i e^{-\beta \epsilon_i} \right)$$

$$\frac{1}{2} \ln \left(\frac{2\pi M}{h^2} \right)^{3/2} - \frac{2M \epsilon}{h^2}$$

where $n_x, n_y, n_z = 0, 1, \dots$

The energy levels can be thought of as quasi-continuous, so that the number of quantum states in the range p to $p + dp$ is $\frac{4\pi p^2 dp}{h^3}$, whence the

$$\text{number of states in the energy interval } \epsilon \text{ to } \epsilon + d\epsilon \text{ is } \frac{(2M)^{3/2}}{h^3} \frac{4\pi}{3} \epsilon^{3/2} d\epsilon.$$

Hence

$$\frac{4\pi V}{h^3}$$

$$\frac{h^3}{2\pi M}$$

$$\frac{2\pi M}{h^3}$$

$$\frac{h^3}{2\pi M}$$

is the average number of quantum states in unit

$$\frac{MkT}{2\pi h^2} \text{ where } n_q = \left(\frac{MkT}{2\pi h^2} \right)^{3/2}$$

volume.

(b) The classical ideal gas satisfies the non-degeneracy condition. The

$$\text{partition function of a sub-system is } z = \sum_i e^{-\beta \epsilon_i} + e^{-\beta \epsilon_2}, z^2 =$$

308 Problem 8 d Solutions on Thermodynamics 4 Statistical Mechanics

$\frac{1}{2} \ln \frac{2\pi M}{h^2}$. Hence the partition function of the system is

The free energy is

$$F = -kT \ln Z = -NkT \ln \left(\frac{V}{n_q} + e^{-\beta \epsilon} \right)$$

The chemical potential is

The pressure is

The entropy is

$$-k \ln N! = Nk$$

$$N \left(\frac{e^{-\beta \epsilon_0}}{1 + e^{-\beta \epsilon_0}} \right)$$

$$+ T \left(\frac{e^{-\beta \epsilon_0}}{1 + e^{-\beta \epsilon_0}} \right)$$

The heat capacity at constant pressure is

a

$$- N A^2 - N A^2$$

$$2kT^2 (1 + \cosh \beta \epsilon_0) \quad 4kT^2 \cosh \beta \epsilon_0$$

2129

(a) Consider an ideal gas of N particles of mass m confined to a volume V at a temperature T . Using the classical approximation for the partition function and assuming the particles are indistinguishable, calculate the chemical potential μ of the gas.

(b) A gas of N particles, also of mass m , is adsorbed on a surface of area A , forming a two-dimensional ideal gas at temperature T on the

surface. The energy of an adsorbed particle is $\epsilon = \frac{p^2}{2m} - \epsilon_0$, where $\mathbf{p} = (p_x, p_y)$ and ϵ_0 is the surface binding energy per particle. Using the same approximations and assumptions as in part (a), calculate the chemical potential μ of the adsorbed gas.

(c) At temperature T , the particles on the surface and in the surrounding three-dimensional gas are in equilibrium. This implies a relationship between the respective chemical potentials. Use this condition to find the mean number n of molecules adsorbed per unit area when the mean pressure of the surrounding three-dimensional gas is p . (The total number of particles in adsorbed gas plus surrounding vapor is N_0).

(Princeton)

Solution:

(a) The classical partition function is

$$N!$$

Thus

$$G = F + pV = -kT \ln Z + NkT$$

$$= -NkT \ln \left(\frac{V}{N} \left(\frac{2\pi m kT}{h^2} \right)^{3/2} \right)$$

$$\mu = -kT \left[\ln \left(\frac{V}{N} \left(\frac{2\pi m kT}{h^2} \right)^{3/2} \right) \right]$$

(b) The classical partition function for the two-dimensional ideal gas is

$$Z = \frac{A^2}{N!} \left(\frac{2\pi m kT}{h^2} \right)^2 e^{N\epsilon_0/kT}$$

$$N!$$

Thus

$$G = F + pA = -NkT \left[\ln \left(\frac{A^2}{N} \left(\frac{2\pi m kT}{h^2} \right)^2 \right) - \frac{\epsilon_0}{kT} \right]$$

(c) The chemical potential of the three-dimensional gas is equal to that of the two-dimensional gas. Note that in the expression of the chemical

310 *Problems & Solutions on Thermodynamics & Statistical Mechanics*

$V kT$
 N v potential for the three-dimensional gas, $\mu = \mu_0 - kT \ln \left(\frac{V}{N} \left(\frac{2\pi m kT}{h^2} \right)^{3/2} \right)$, and in that for the two-

A 1

N_n

dimensional gas, $\mu = \mu'$. Since the two chemical potentials have the same value, one obtains

2130

A simple harmonic one-dimensional oscillator has energy levels $E_n =$

$(n + 1/2)Aw$, where w is the characteristic oscillator (angular) frequency

and $n = 0, 1, 2, \dots$

(a) Suppose the oscillator is in thermal contact with a heat reservoir at temperature T , with $\beta Aw \ll 1$. Find the mean energy of the oscillator as a function of the temperature T .

kT

Aw

(b) For a two-dimensional oscillator, $n = n_x + n_y$, where

$n_x = 0, 1, 2, \dots$ and $n_y = 0, 1, 2, \dots$, what is the partition function for this case for any value of temperature? Reduce it to the degenerate case

$w_x = w_y$.

(c) If a one-dimensional classical anharmonic oscillator has potential energy $V(z) = \frac{1}{2}cz^2 - gz^3$, where $gz^3 \ll \frac{1}{2}cz^2$, at equilibrium temperature T , carry out the calculations as far as you can and give expressions as functions of temperature for

1) the heat capacity per oscillator and

2) the mean value of the position z of the oscillator.

(UC, Berkeley)

tw

(a) Putting $a = Aw$, one has

kT

Solution:

Statistical *Physic8* 311

(b) There is no difference between a two-dimensional oscillator and two independent one-dimensional oscillators, then the partition function is

$$Z = \int \int e^{-\beta(\frac{1}{2}m\dot{x}^2 + \frac{1}{2}m\dot{y}^2 + \frac{1}{2}c(x^2 + y^2) - g(x^3 + y^3))} dx dy$$

$$Z = Z_x Z_y$$

When $w_x = w_y = a$, we have

$$Z_x = Z_y = Z_1$$

$$Z_1 = \int e^{-\beta(\frac{1}{2}m\dot{x}^2 + \frac{1}{2}m\dot{y}^2 + \frac{1}{2}cx^2 - gx^3)} dx$$

$$Z_1 = \int e^{-\beta(\frac{1}{2}m\dot{x}^2 + \frac{1}{2}cx^2)} e^{\beta gx^3} dx$$

$$Z_1 = \int e^{-\beta(\frac{1}{2}m\dot{x}^2 + \frac{1}{2}cx^2)} dx \cdot \int e^{\beta gx^3} dx$$

(c) 1) We calculate the partition function

$$Z = \int \int \exp[-(\frac{1}{2}m\dot{x}^2 + \frac{1}{2}m\dot{y}^2 + \frac{1}{2}c(x^2 + y^2) - g(x^3 + y^3))/kT] dx dy$$

(Note that the kinetic energy term has not been included in the expression, this is done by adding kT in the heat capacity later.) The non-harmonic term $(\exp(gx^3/kT) - 1)$ is a small quantity in the region of motion. Using Taylor's expansion retaining only the lowest order terms, we get
